PRICE, RICHARD (1723–1791)

Richard Price, a Welsh dissenting preacher, moral philosopher, and actuary, was born at Tynon, Llangeinor, Glamorganshire. His father, Rees, was a dissenting minister with extreme Calvinist opinions. Richard Price was educated at a number of different academies, finally entering Coward's Academy in London, where he remained for the years 1740–1744. He was ordained at the age of twenty-one and began his ministerial career as a domestic chaplain. He later served a number of London congregations, notably those at Stoke Newington, where he lived, and at the Gravel-Pit Meeting House in Hackney. Price was buried in the cemetery at Bunhill Fields; his friend Joseph Priestley preached the funeral oration.

In addition to his writings on moral philosophy, Price wrote with considerable influence on financial and political questions. His papers on life expectancy and on calculating the values of reversionary payments were instrumental in reforming the actuarial basis of the insurance and benefit societies of the time. His paper on the public debt is said to have led William Pitt, the prime minister, to reestablish the sinking fund to extinguish England's national debt. In his pamphlet *Observations on*

the Nature of Civil Liberty, the Principles of Government, and the Justice and Policy of the War with America (London, February 8, 1776), Price defended the American cause. The widespread circulation and generally favorable acceptance of this work is said to have encouraged the American decision for a declaration of independence. Price had become friendly with Benjamin Franklin during the latter's stay in London, and in 1778 the Continental Congress moved to grant Price American citizenship if he would come to America and serve as an adviser on the management of American finances. He was grateful for the invitation but did not accept it. Price also regarded the French Revolution with approval, which he expressed, along with an appeal for reform in England, in his *Discourse on the Love of Our Country* (1789). Edmund Burke's *Reflections on the Revolution in France* (1790) was written in reply.

Price is also the author of *Four Dissertations*: I. "On Providence"; II. "On Prayer"; III. "On the Reasons for expecting that virtuous Men shall meet after death in a State of Happiness"; IV. "On the Importance of Christianity, the Nature of Historical Evidence, and Miracles" (London, 1767). In the fourth of these dissertations Price criticized David Hume's "Of Miracles." Hume was grateful for the civility with which Price argued, and he wrote

to Price that the light in which he put this controversy was “new and plausible and ingenious, and perhaps solid. But I must have some more time to weigh it, before I can pronounce this judgment with satisfaction to myself.”

MORAL PHILOSOPHY

Price’s contribution to moral philosophy is *A Review of the Principal Questions in Morals* (London, 1758; corrected editions in 1769 and 1787). Price criticized the moral-sense doctrines of Francis Hutcheson in order to clear them away and make room for an account of immutable right and wrong, derived from Samuel Clarke.

Price says that we may have three different perceptions concerning the actions of moral agents. We may notice whether they are right or wrong, whether they are beautiful or ugly, and whether they are of good or ill desert. By talking of perceptions here, he shows that he has accepted the premise, of Lockean origin, that all knowledge is to be accounted for as some kind of perception by one of our faculties. Thus, Price’s first question, “How do we know right?” is treated as a search for the faculty by means of which we obtain our ideas of right and wrong. He considers Hutcheson’s answer that our moral ideas come to us by the way of a moral sense, and he understands Hutcheson to be claiming that this sense is “a power within us, different from reason; which renders certain actions pleasing and others displeasing to us.”

Price objects to this doctrine because of certain consequences that he believes are implied by it. Our approval and disapproval of actions appear to depend on the way our minds work or, to carry the matter back a step, on the way God has made them to work. Thus, our judgments of right and wrong depend on the mere good pleasure of our Maker, who created us in a certain way. But if he had pleased, he might have made us to be pleased or displeased by quite different actions, even actions contrary to those that now please and displease us. Thus, right and wrong would be only matters of taste, only a certain effect in us, and nothing in actions themselves.

For his part, Price is convinced that morality is equally unchangeable with all truth and that right and wrong are real characteristics of actions and not mere sensations derived from the particular way in which our minds are framed. To show the immutability of right and wrong, Price argues that these ideas are derived not from a special sense but from the understanding. As Price sees it, the only debatable issue in morals is not what actions are right and wrong but what is the faculty by which we discern right and wrong.

Price prefaces his argument for regarding the understanding as our moral faculty with the preliminary claim that the understanding is a source of new ideas. He objects to interpreting John Locke as saying that sensation and reflection are the sources of all our ideas. Price argues that Locke may have meant only that all our ideas are ultimately grounded on ideas derived from sensation and reflection. Thus, Price makes room for certain new ideas that may arise as the understanding compares the objects of thought and judges them. Some of these new ideas are solidity, inertia, substance, accident, duration, space, cause or power, entity, possibility, and actual existence.

Price locates these new ideas in a revised classification of simple ideas. He divides simple ideas into those implying nothing real outside the mind and those that denote real and independent existence distinct from sensation. The first class of simple ideas consists, on the one hand, of tastes, smells, and colors and, on the other, of such notions as order, happiness, and beauty. The second class of simple ideas has three subclasses: the real properties of external objects, such as figure, extension, and motion; the actions and passions of the mind, such as volition, memory, and so on; and those new ideas noted above which arise as the understanding considers the ideas it has been supplied with. It is important to note that Price does not regard the second class of simple ideas as constructions of the mind. The real properties of external objects are in the objects, and such new ideas as cause, duration, and space are of properties in a real world.

Armed with his reclassification of simple ideas, Price is now prepared to locate our ideas of moral right and wrong in the scheme and thus establish that they are perceptions of the understanding. Price first considers the question of whether moral right and wrong are simple ideas. He declares that they must be, for we cannot give definitions of them that are more than synonymous expressions. It is Price’s recognition of this point which has led contemporary students to declare him one of the first to recognize the naturalistic fallacy, although he does not use that term. Having established that our ideas of right and wrong are simple ideas, Price then locates them in his scheme as two of those new ideas which arise in the understanding.

Hutcheson had simply assumed that if right and wrong are immediately perceived, they must be perceptions of an implanted sense. But the question of how we perceive these ideas may be settled by simply considering the nature of our own perceptions.

Let anyone compare the ideas arising from our *powers of sensation*, with those arising from our *intuition of the natures of things*, and enquire which of them his ideas of right and wrong most resemble.... It is scarcely conceivable that anyone can impartially attend to the nature of his perceptions, and determine that when he thinks gratitude or beneficence to be *right*, he perceives nothing *true* of them, and *understands* nothing, but only receives an impression from a sense.

Price notes that some impressions of pleasure or pain, satisfaction or disgust, generally attend our perceptions of moral right and wrong; the proponents of a moral sense may have confused these impressions with our actual perceptions of right and wrong.

But there is an assumption in Price's own system on which much depends and for which he offers insufficient argument. He tells us that "all actions undoubtedly have a *nature*. That is, *some character* certainly belongs to them, and somewhat there is to be *truly* affirmed of them." It is the task of the understanding to perceive these truths. Price regards actions in this way because it enables him to say that their rightness or wrongness is in them, not in the mind of the person judging the actions, but apart from noting the advantage to his own moral philosophy, Price offers no justification for the claim that actions have natures. It is unfortunate that he does not, for he rests his contention that morality is eternal and immutable on this claim.

When Price turns to our ideas of the beauty and deformity of actions, the second kind of perception of actions which he promised to account for, he finds that these perceptions are feelings of delight or detestation which may accompany our perceptions of the rightness or wrongness of actions. These feelings of delight and detestation are the effects on us of the actions we consider, and it is very likely that they arise from an arbitrary structure of our minds, which may be called a sense. Price allows that there is a distinction between noting that an action is right and approving it. We are made, however, in such a way that we cannot perceive an action to be right without approving it, for in humans it is necessary that the rational principle, or the intellectual discernment of right and wrong, should be aided by instinctive determinations. When these feelings of the heart support the perceptions of the understanding, we are provided with the motivation for moral behavior. Here Price agrees with Hutcheson, pointing out that he has never disputed that we owe much to an implanted sense and its determina-

tions. He means to resist only the claim that we owe our knowledge of right and wrong to such a sense.

Our ideas of the good and ill desert, the third sort of perception concerning actions which Price notes, carry the mind to the agent. He finds that we cannot but love a virtuous agent and desire his happiness above that of others. Quite apart from any advantage which we may gain from someone else's virtuous behavior, we have an immediate approbation of making the virtuous happy and of discouraging the vicious.

Price distinguishes between abstract and practical virtue. Abstract virtue denotes "what an action is independently of the sense of an agent; or what, in itself and absolutely, it is right such an agent, in such circumstances, should do." But Price recognizes that the actual practice of virtue depends on the opinion of the agent concerning his actions. Thus, an agent may be mistaken about his circumstances but sincere about what he believes he ought to do. In this respect practical virtue may diverge from abstract virtue but be no less obligatory insofar as the agent acts from a consciousness of rectitude. The ideal state of affairs is a correspondence of practical virtue with abstract virtue. Its achievement depends on the liberty and intelligence of the agent. These constitute the agent's capacity for virtue, and intention gives virtue actual being in a character. Price takes a short way with the question, "Why be moral?" "The knowledge of what is right, without any approbation of it, or concern to practise it, is not conceivable or possible. And this knowledge will certainly be attended with *correspondent, actual practice*, whenever there is nothing to oppose it." Why a person chooses to do what he knows he should do is a question "which need not and should not be answered."

Benevolence is not the sole virtue. We also have duties to God and to ourselves, and there is room for many other sorts of good behavior, such as veracity, sincerity, and gratitude. As a measure of virtue Price offers the rule that "the virtue of an agent is always less in proportion to the degree in which natural temper and propensities fall in with his actions, instinctive principles operate, and rational reflexion on what is right to be done, is wanting."

Price discusses at length the relation of morality to the divine nature. Just as moral right and wrong are independent of man's mind, they are also absolutes for God. Were this not so, there would be no sense in which God's will could be good.

FREEDOM OF THE WILL

Price and Priestley published a set of letters as *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity* (London, 1778). The correspondence had its origin in Price's criticism of Priestley's *Disquisitions Relating to Matter and Spirit*. The letters cover the nature of matter, the human mind, the mortality of the soul, the essence of the deity, and the doctrine of necessity. The last topic is the one that is treated in the most interesting way. Priestley contended that there can be no human liberty because "liberty" must mean someone's willing without a motive, which he regards as impossible. Price enlarges on the account of liberty that he offered in *A Review of the Principal Questions in Morals*. He argues that human agents are not physical objects but unique entities capable of self-determination. Consider the difference between a man who is dragged by a superior force and a man who follows a guide for a reward. Both of these examples may be certainties, but having different foundations, they are of totally different natures. "In both cases the man might in common speech be said to *follow*; but his following in the one case, however certain in event, would be *his own* agency: In the other case, it would be the agency of another. ... In the one case, superior power moves him: In the other he moves himself."

Bibliography

Price's *Works* were published in 10 volumes (London, 1816), with a memoir of his life by W. Morgan. *A Review of the Principal Questions in Morals* has been published with a critical introduction by D. D. Raphael (Oxford, 1948). This is a reprint of the third edition (1787) with an appendix and "A Dissertation on the Being and Attributes of the Deity."

For biography, see Carl B. Cone, *Torchbearer of Freedom, the Influence of Richard Price on Eighteenth Century Thought* (Lexington: University of Kentucky Press, 1952). Other works on Price include Joseph Priestley, *A Discourse on the Occasion of the Death of Dr. Price* (London, 1791); Leslie Stephen, *History of English Thought in the Eighteenth Century* (London, 1876; 2nd ed., London, 1902); and Roland Thomas, *Richard Price* (London: Oxford University Press, 1924).

Elmer Sprague (1967)

PRIESTLEY, JOSEPH

(1733–1804)

Joseph Priestley, the English scientist, nonconformist minister, educator, and philosopher, was born at Birstall, Yorkshire, the son of a cloth dresser. His mother died in 1740, and in 1742 Priestley was adopted by a childless well-to-do aunt, Mrs. Keighley, a convinced but unbigoated Calvinist. A sensitive child, Priestley suffered greatly because he could not convince himself that he had experienced the "new birth" essential, on the Calvinist scheme, for his salvation. As a result of these childhood miseries Priestley was left, he tells us, with "a peculiar sense of the value of rational principles of religion" as opposed to the "ignorance and darkness" of Calvinism.

Until the age of sixteen Priestley was educated at a conventional grammar school. For the next three years, his health being too poor for regular studies, he in large part educated himself, reading his way into mathematics, physics, and philosophy and undertaking the study of European and Middle Eastern languages. In 1752 his health improved and he entered Daventry Academy, a university-type institution set up by nonconformists because Oxford and Cambridge would not admit nonconformists to a degree.

At Daventry the emphasis was on free discussion, and the curriculum was considerably broader than at Oxford or Cambridge. Priestley was introduced to David Hartley's *Observations on Man* (1749) and was at once—and permanently—converted to Hartley's general outlook. The simplicity and generality of Hartley's associationist psychology appealed to Priestley's maturing scientific instincts; it provided a theoretical foundation for his belief in perfectibility through education; and it offered a psychological alternative to the doctrine of free will, which Priestley's reading of Anthony Collins's *Philosophical Inquiry concerning Human Liberty and Necessity* (1714) had already caused him to reject.

In 1755 Priestley entered the ministry, taking over a decaying congregation at Needham Market, Suffolk. Stammering and unorthodox, he was not a success as a minister. He moved in 1758 to a more sympathetic but equally impoverished congregation at Nantwich in Cheshire. In an attempt to increase his income he set up a school where, perhaps the first to do so, he taught experimental science with the help of an "electrical machine" and an air pump.

Appointed in 1761 as "tutor of the languages" at Warrington Academy in Lancashire, Priestley taught oratory, literary criticism, grammar, history, and law, as well

as languages. Characteristically, on all these latter topics Priestley developed ideas that he sooner or later published. *The Rudiments of English Grammar* (1761), many times reprinted, is typical of his innovating boldness, insofar as he tried to simplify English syntax by removing from it the complications introduced by classically trained grammarians. His *A Chart of Biography* (1765) and *A New Chart of History* (1769) were even more enthusiastically received; they won for him not only his sole academic distinction, the doctorate of laws of the University of Edinburgh, but also his fellowship of the Royal Society.

Priestley's days of relative isolation were now over. In 1762 he married an ironmaster's daughter, Mary Wilkinson, an intelligent woman with a sense of humor and considerable force of character—qualities she was to need in the years to come. His duties at Warrington left him free to visit London for a month each year, where he came into contact with an active group of scientists, philosophers, and political thinkers, including Benjamin Franklin and Richard Price. Franklin encouraged Priestley's project of writing a history of electrical experiments. The work that resulted, *The History and Present State of Electricity, with original Experiments* (1767), is a notable contribution to the history of science. Describing a number of important original experiments, it is also in some respects the most theoretically adventurous of Priestley's scientific works. It contains as well Priestley's reflections on the use of hypotheses in scientific procedures as a guide to experimentation.

EDUCATION AND GOVERNMENT

Like many of his fellow dissenters, Priestley was greatly interested in educational reform. Education had, he thought, thus far concentrated unduly on the needs of the clergy. His *An Essay on a Course of Liberal Education for Civil and Active Life* (1765) is a plea for a curriculum that should be suitable for men of affairs, emphasizing history and public administration rather than the classical languages. Priestley did much to encourage the teaching of history in the nonconformist academies. A set of lectures that he delivered at Warrington (published in 1788 as *Lectures on History and General Policy*) provided not only the academies but also the new American colleges with a text suitable for their needs; it was, indeed, recommended even at Cambridge. It is a summary account of the main historical sources, with an emphasis on commerce, law, and administration, rather than a historical textbook of the ordinary kind.

Priestley's political theory was closely related to his interest in education and his experience as a member of a minority group. In an appendix to his *Essay on a Course of Liberal Education* he developed an argument against the introduction of a state system of education, which would inevitably, he thought, favor the *status quo* and produce a quite undesirable uniformity of conduct and opinion. Like John Stuart Mill after him, Priestley gloried in diversity; uniformity, he said, is "the characteristic of the brute creation."

These reflections were more fully worked out in *An Essay on the First Principles of Government* (1768), which bears the subtitle *On the Nature of Political, Civil and Religious Liberty*. For Priestley, the preservation of civil liberty was the crucial political issue. Deciding who should participate in government—who, that is, should possess political, as distinct from civil, liberty—was, he thought, a practical matter, to be settled by considering what groups in the community are most likely, if they possess political power, to act for the greatest happiness of the greatest number. Such groups remain entitled to power only as long as they continue so to act. Legislation, on Priestley's view, should be kept to the minimum. What that minimum is cannot be determined a priori but only as a result of political experiment. But we can see at once, Priestley thought, that legislation that restricts civil and religious liberty is bound to be against the interests of the community. Unlike most nonconformist upholders of toleration and unlike his master John Locke, Priestley was uncompromising on this point; he upheld unbounded liberty of expression even to atheists and Roman Catholics.

In Priestley's eyes, the noblest of occupations was that of the clergyman, not the lecturer, and in 1767 he accepted a call to Mill Hill, Leeds, a congregation to whom his religious views were exceptionally congenial. The years Priestley spent at Mill Hill were extremely important in his development; his salary, although small, sufficed for his needs, and his duties left him considerable leisure.

UNITARIANISM

Priestley had long before abandoned both the doctrine of the atonement, on which he wrote critically in *The Scripture Doctrine of Remission* (1761), and orthodox Trinitarianism. Now he took what was to be the final step in his transition from Calvinism to Unitarianism. Christ, he argued, although the Messiah, was a man, and not even a perfect man. Priestley's subsequent theological writings were in large part an attempt to prove—most maturely in

his *History of Early Opinions concerning Jesus Christ* (1786)—that Unitarianism was the doctrine of the early church. He defended his unorthodoxies both against clerical attack, as in his *Letters to Dr. Horsley* (1783–1786), and, as in his *Letters to a Philosophical Unbeliever* (Pt. I, 1780; Pt. II, 1787), against those who, like Edward Gibbon, could not understand why Priestley did not make a complete break with Christianity. Priestley valued his theological writings above all his other work. A firm belief in Providence is everywhere evidenced in his writings. Few men have committed themselves so often and so absolutely to the doctrine that “all is for the best in the best of all possible worlds,” although he also believed that the future world could—and therefore would—be better.

SCIENTIFIC ACHIEVEMENT

It was as a scientist that Priestley won his international reputation. He published in 1772 what was intended to be the second section of a general history of science, *The History of the Present State of the Discoveries relating to Vision, Light and Colours*; but this work, invaluable though it still is to historians of science, did not arouse a great deal of interest. Priestley therefore abandoned his large-scale historical project and concentrated instead on chemistry. His first chemical publication, in 1772, was of an unusually practical character: It described a method of producing “mephitic julep,” or soda water. But it was the paper “On Different Kinds of Air,” which he read in that same year to the Royal Society,” that at once established his reputation as a chemist. In 1774 he prepared the first edition of *Experiments and Observations on Different Kinds of Air*; this he republished in a series of editions, with important changes in contents, in method of organization, and even in title, until 1790.

By the end of that period Priestley, following up the work of Joseph Black and Henry Cavendish, had considerably enlarged our knowledge of the chemical properties of gases. He differentiated between nine gases, of which only three had previously been known to science, and described a method of collecting them. Of particular importance was his preparation of “dephlogisticated air” (oxygen), which he produced on August 1, 1774, by heating red mercuric oxide. It then became clear that air was not an element. Priestley went on to examine the properties of oxygen; in a series of chemicobiological experiments he brought out its importance for animal life.

As a resourceful experimenter, using simple and economical methods, Priestley has had few equals. But it was left to others, to Cavendish and Antoine Lavoisier, to appreciate the theoretical significance of his work. Priest-

ley had isolated oxygen and had observed its importance in combustion; he had passed a spark through a mixture of hydrogen and oxygen and had noticed that dew was formed. Yet his last scientific work (1800) bore the title *The Doctrine of Phlogiston established and that of the Composition of Water refuted*. Although he had himself carried out important quantitative experiments, he did not appreciate the significance of the quantitative considerations by which Lavoisier overthrew the phlogiston theory.

PHILOSOPHY

Much of Priestley’s most important scientific work was carried out at Shelburne, where from 1772 until 1780 he acted as “librarian and literary companion” to the Earl of Shelburne. During these same years Priestley embarked upon his most substantial metaphysical works. He began in 1774 with *An Examination of Dr. Reid’s Inquiry into the Human Mind on the Principles of Commonsense, Dr. Beattie’s Essay on the Nature and Immutability of Truth, and Dr. Oswald’s Appeal to Commonsense on Behalf of Religion*, commonly referred to as *An Examination of the Scotch Philosophers*. This is a vigorous polemic, which sets out to demonstrate the superiority of Hartley’s psychology to the philosophy of the Scottish commonsense school, a philosophy that Priestley thought obviously reactionary insofar as it substituted for the simple Locke-Hartley theory of mind “such a number of independent, arbitrary, instinctive principles that the very enumeration of them is really tiresome.” All the so-called instinctive beliefs of common sense can, Priestley set out to show, be derived from the operations of associative principles working on the materials provided by sensation. He came to regret in later life the tone of this publication but never its doctrines.

MATERIALISM. Hoping to make Hartley’s views better known, Priestley published an abridged version of Hartley’s *Observations on Man* in 1775 as *Hartley’s Theory of the Human Mind on the Principle of the Association of Ideas*. In his preface, Priestley somewhat tentatively suggested that all the powers of the mind might derive from the structure of the brain. Even as a suggestion this created a considerable uproar, but Priestley was not to be intimidated by clerical clamor. Convinced that materialism was the natural metaphysical concomitant of Hartley’s associative psychology, he set out, therefore, in his *Disquisitions Relating to Matter and Spirit* (1777) to demonstrate that materialism was theologically, scientifically, and metaphysically superior to orthodox dualism.

On the theological side, materialism had commonly been objected to on the ground that it is incompatible with immortality. Man, Priestley replied, is not “naturally” immortal; he is immortal only because, as we know from revelation, God chooses to resurrect him; this resurrection is of the body and therefore also of the body’s mental powers. As for the commonplace metaphysical objections to materialism, these are based, according to Priestley, upon an untenable conception of matter as being by nature inert and therefore incapable of exerting mental activity. To such a concept of matter Priestley opposed the physical theories of his friend and fellow scientist John Michell and the Jesuit mathematician Roger Boscovich. Material objects, on their view, are centers of force; if this is the nature of matter, Priestley argued, there is no good reason for denying that mental operations are part of the activity of a material object. On the other hand, there are very good reasons for objecting to the traditional dualism, which is quite incapable of explaining how mind and body can enter into any sort of relationship.

DETERMINISM. Priestley had been a determinist long before he became a materialist, but not until 1777, in *The Doctrine of Philosophical Necessity Illustrated*, did he fully present his case against free will; indeed, even then he thought of himself as supplementing Thomas Hobbes, Collins, David Hume, and Hartley with illustrations rather than as working out an entirely independent position. The doctrine of free will, he argued, is theologically objectionable because it cannot be reconciled with the existence of an all-seeing Providence; from a metaphysical standpoint, it makes human actions quite unintelligible, and ethics has no need of it. As a basis for our everyday moral judgments, the distinction between acting voluntarily and acting under compulsion is certainly important, but this distinction does not, according to Priestley, rest upon a metaphysical conception of free will.

Priestley’s metaphysical unorthodoxies considerably disturbed his old friends, provoking a candid but good-tempered correspondence with Richard Price, published in 1778 as *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity Illustrated*. Developing his views on the relation between moral judgments and determinism, Priestley admitted that the determinist will prefer to avoid describing people as blameworthy or praiseworthy. He will say of them, rather, that they have acted, or have not acted, from good principles—from principles, that is, that are conducive to the general happiness. But the determinist’s different method of describ-

ing moral conduct has, Priestley thought, no practical consequences, and if determinism is in some respects inconsistent with everyday usage, this is even more true of libertarianism.

LATER YEARS

There was a real risk, however, that Priestley’s reputation for materialism might endanger the earl of Shelburne’s political ambitions. Perhaps for this reason Priestley and Shelburne parted amicably in 1780, when Priestley, refusing Shelburne’s offer of a post in Ireland, took up residence in Birmingham. There he had a circle of congenial friends who were prepared to offer him financial as well as intellectual support. He became a member of the Lunar Society, with which were associated men of the caliber of Erasmus Darwin and James Watt, and he enjoyed the friendship and help of the scientifically minded potter Josiah Wedgwood, who supplied him with apparatus specifically designed for his chemical experiments. Much of Priestley’s scientific work in this period, under Alessandro Volta’s influence, conjoined his two main scientific interests: electricity and gases. He examined the effect of passing electrical sparks through a variety of gases and studied their thermal conductivity.

He was by no means unsympathetic to the laissez-faire sociopolitical attitude of Birmingham industrialists. In *Some Considerations on the State of the Poor in General* (1787) he strongly criticized the poor laws and elsewhere opposed apprenticeship laws and laws for regulating interest rates. On his view, any sort of social welfare legislation “debased the very nature of man” by treating him as someone who had to be provided for. Although Priestley warmly supported schemes for cooperative insurance against hardship, he was opposed to any legislation that might diminish independence or increase the power of the state over individuals.

POLITICAL RADICALISM. In general terms, Priestley’s life at Birmingham was a continuation and development of his earlier activities; theological controversy continued to be his main interest. But one event transformed his life and modified his political attitudes: the French Revolution. Reacting to that revolution, the British government became steadily more intolerant and conservative, and Priestley came to think that extensive political innovations were a necessary condition for the preservation of civil liberty. He moved toward political radicalism of the nineteenth-century kind in his *Letters to Edmund Burke occasioned by his Reflections on the Revolution in France* (1791) and in the anonymously published *A Political Dia-*

logue on the General Principles of Government (1791). He had formerly been accustomed to describe himself as “a Unitarian in religion but a Trinitarian in politics” because he had accepted the view that liberty rested on the balance between king, Commons, and House of Lords. He now came to feel that there should be but one source of political power, the will of the people as it would be represented in a reformed House of Commons.

On July 14, 1791, the Friends of the Revolution organized a dinner at Birmingham (Priestley was not present) in order to commemorate the fall of the Bastille. This was the last straw. With the encouragement, it would seem, of the authorities, an angry mob attacked the non-conformist chapels, then turned their attention to Priestley’s house, destroying his books and furniture. Priestley was persuaded by his friends to leave Birmingham for London where he was, however, shunned by his scientific colleagues.

LIFE IN AMERICA. For some years, Priestley had been contemplating migration to the United States, where his three sons had already gone. In 1794 he left for New York and finally settled in Northumberland, Pennsylvania. There, still supported by his old friends, he continued to experiment and to write, mainly on theological questions.

He was disappointed, however, by the orthodoxy of the American clergy and alarmed by the growth of intolerance in the United States. Although he took no part in politics, he wrote an uncompromising exposition of his political and religious views in *Letters to the Inhabitants of Northumberland* (1799). There was talk of his being deported under the Aliens Act, but John Adams would not permit the application of the act to “poor Priestley.” With the election of Thomas Jefferson to the presidency, Priestley was not only secure but also at last on good terms with authority. Jefferson consulted him on educational questions, and Priestley’s *Socrates and Jesus Compared* (1803) precipitated Jefferson’s “Syllabus” of his religious beliefs. Another of Priestley’s works, *The Doctrines of Heathen Religion Compared with those of Revelation* (1804), awoke in Adams an enthusiasm for comparative religion. Priestley’s last years, from 1801 until his death, were marred by ill health and bereavements, but his diversified intellectual interests remained with him until the end.

Bibliography

Priestley’s scientific writings have never been collected. The standard edition of his philosophical, theological, and miscellaneous writings is *The Theological and Miscellaneous Works of Joseph Priestley*, edited by John Towill Rutt, 25 vols. in 26 (London: G. Smallfield, 1817–1832). John Arthur Passmore, *Joseph Priestley* (New York, 1965) includes a short list of Priestley’s writings, an introductory essay, and selections from his major works.

See also Thomas Henry Huxley, “Joseph Priestley,” in *Science and Culture* (London, 1881); Thomas Edward Thorpe, *Joseph Priestley* (New York: Dutton, 1906); Edgar Fahs Smith, *Priestley in America, 1794–1804* (Philadelphia: P. Blakiston’s Son, 1920); Wallace Ruddell Aykroyd, *Three Philosophers: Lavoisier, Priestley and Cavendish* (London: Heinemann, 1935); Arthur Handley Lincoln, *Some Political and Social Ideas of English Dissent, 1763–1800* (Cambridge, U.K., 1938); Francis Edward Mineka, *The Dissidence of Dissent* (Chapel Hill: University of North Carolina Press, 1944); Stephen Edelston Toulmin, “Crucial Experiments: Priestley and Lavoisier,” in *Journal of the History of Ideas* 18 (2) (1957): 205–220; and the detailed bibliographies in the *Dictionary of National Biography* and the *Dictionary of American Biography*.

John Passmore (1967)

PRIMARY AND SECONDARY QUALITIES

The distinction between “primary and secondary qualities,” first stated and thus named by Robert Boyle, received its classical formulation in John Locke’s *Essay*. There Locke states that apart from ordinary causal properties or “powers,” material objects possess five primary qualities—extension (size), figure (shape), motion or rest, number, and solidity (impenetrability)—and many secondary qualities, such as color, taste, smell, sound, and warmth or cold. This distinction was made in the context of representative realism; that is, it was presupposed that the qualities of objects are quite distinct from, and are in fact causes of, “ideas” (representations or *sensa*), which are the only immediate objects of sensory awareness. The basis of the distinction was twofold. First, perceived size, shape, motion, number, and solidity are ideas caused by and exactly resembling the corresponding primary qualities of objects; perceived color, taste, smell, sound, and so on are caused by, but do not resemble, the corresponding secondary qualities. Second, the primary qualities are inseparable from matter and are found in every part of it;

the secondary qualities are not true qualities of matter but are merely powers in the objects to produce sensory effects in us by means of the primary qualities in their minute parts. Thus, red as experienced (*idea* or *sensum*) is the effect of the secondary quality red, which is merely the power possessed by a special texture or surface structure of the object to reflect certain light frequencies and to absorb others.

This formulation is rather clumsy, and since George Berkeley the custom has been to apply the first part of the distinction to the qualities of the ideas or *sensa*. The primary or spatiotemporal qualities of these data may then be said to characterize the object as well, for instance, the *sensum* is square and so is the object; but the secondary qualities are said not to characterize the object at all except in a derivative way, for instance, the *sensa* may be red and fragrant, but the object itself is intrinsically neither colored nor scented; it is red and fragrant only in the secondary sense that it causes the appropriate data of color and smell in the percipient. The doctrine is thus essentially the same as Locke's, but the language is slightly different. This second formulation will be used here.

Though Boyle and Locke invented and popularized the distinction and the terminology of primary and secondary qualities, the distinction dates back in principle to Democritus, who said that sweet and bitter, warm and cold, and color exist only by convention (*νόμος*), and in truth there exist only the atoms and the void (Fr. 9, Diels and Kranz). The distinction was revived by Galileo Galilei and accepted by René Descartes, Isaac Newton, and others.

ARGUMENTS FOR THE DISTINCTION

RELATIVITY AND MEASUREMENT. The relativity argument is the most important one: Secondary qualities are affected by the condition of our sense organs and nervous system, by our distance from the object or its motion relative to us, by the lighting or by such intervening media as fog. Since secondary qualities thus vary according to, and depend for their nature on, factors quite external to the physical object, they cannot be intrinsic properties of it. This point was elaborated by Locke in various examples, two of which follow: (a) If one takes three bowls of water, one judged hot, one judged cold, and one judged medium, and places one hand in the hot water and the other hand in the cold, and then transfers both hands to the middle bowl, the water in that bowl will feel hot to the hand that has been in the cold water and cold to the hand that has been in the hot water. But since it cannot be both hot and cold, hot and cold are therefore not intrinsic

properties of the water. (b) Marble is not colored in the dark; its color appears only in the light. But presence or absence of light cannot alter its real properties, so that the perceived color cannot be included among them.

If we grant the position of representative realism that hot, cold, and color, as experienced, are qualities of ideas or representations, then it is plausible to suppose on these grounds that they do not also characterize objects or resemble properties of objects. (Locke does not always make it clear that representative realism is to be presupposed). But this claim is apparently open to the insuperable objection, stated by Berkeley, that the primary qualities also vary: The object's apparent shape or size varies just as much as its color or sound. This would mean that shape and size as perceived do not characterize objects or resemble the actual properties of the object, thus subverting the whole basis of the distinction. That Locke did not see this may have been partly because he felt that he had to argue against the commonsense assumption that all sensible qualities characterize objects, and partly because the belief that primary qualities characterize all matter was apparently guaranteed by the physics of his day.

Although this objection is valid against Locke's position, it does not destroy the distinction between the primary and secondary qualities, which it is natural to recast and support by a revised relativity argument. This new point is that, in contrast with the secondary qualities, the main primary qualities—shape, size, and motion—can all be measured (solidity cannot, but it is dubious anyhow, in that most physical objects, even atoms, are far from solid or impenetrable; number, whether there is one object or two, seems scarcely a quality at all; strictly also in the case of shape, what is measured are various dimensions—diameters, angles, and so on—of the object, and supporters of the distinction must maintain that these are the *differentiae* of the shape). A plate may look elliptical, but by measuring its diameters and seeing that they are equal, we can establish that it is round; one man may look taller than another, but their relative heights may be settled by measurement, as can the speed of objects relative to the earth. The measured size and shape of a plate may thus be held to characterize it, and the sensible size and shape may agree with and resemble them, so that one can say that size and shape (and motion) are primary. Nevertheless, only in favorable circumstances does a given primary sensible quality also characterize the object (for instance, both object and *sensum* are round); otherwise, there is only a projective relationship, as between elliptical *sensum* and round object.

Measurement is objective and does not vary significantly because it is an operation that depends on the coordination of a number of separate perceptions and that may be performed by a number of different persons. Consequently, variations due to the measurer on any particular occasion are compensated for and do not affect the final result, and the various actions confirm that one is not simply establishing the qualities of representations. Measurement also leads to conclusions regarding the dimensions and positions of objects in physical space that can be verified by further activities or operations, such as fitting the objects together, moving one's hand between them, rolling an object to confirm that it is round, and so on. By contrast, the variation found in the sensory qualities seems to be caused by their being simply the content of one single act of perception limited to one person at one time.

If all this is so, the list of primary qualities must be somewhat amended. Shape, size, and motion remain, but one should substitute mass for solidity. Temperature is more difficult: Since it can be measured, it seems at first primary. But what is measured is the property of causing expansion in fluid or metal; this property in no way resembles felt warmth, and in physical theory it is a form of energy. Hence, temperature should not be regarded as a separate primary quality. Material objects do, of course, possess many other properties—causal and dispositional ones, for example—as Locke realized by his doctrine of “powers,” but part of the distinction is that only the primary ones are intrinsic (that is, possessed without reference to other objects) and that all such powers are ultimately due to patterns of primary qualities. Even so, the distinction would have difficulty in coping with some intrinsic “scientific” properties, such as energy or electric charge.

Apart from this, various objections have been made to the distinction in terms of measurement. First, measured motion and size must be stated in terms of some standard, such as a yard or meter; hence, they are purely relational and are not intrinsic properties of the object. But one can reply that it is only the description or labeling of the measurement that is thus relational; the motion or extension labeled, which is actually measured, seems intrinsic to the object.

Second, since colors and sounds may be measured, are they not also primary? But this objection seems based on a misunderstanding of the processes of measurement, for one way of “measuring” color might be to compare a given shade with a standard on a shade card; but that would be like comparing the sensible size of two objects, not meas-

uring them. Proper measurement goes beyond this kind of sensory experience, and even if one gives the shade a number, one cannot calculate with the results as one can with the dimensions of objects. Normally, however, measurement of colors or sounds is either the measurement of the amplitudes or lengths of light waves or sound waves, or a mixture of wave measurement and the comparison of experiences. If one brings up a decibel meter and says that the sound to be measured is 80 decibels, it is the amplitude of the sound waves that is ultimately responsible for the movement of the pointer to 80. It should be noted, however, that the logarithmic scale is used because of a characteristic of human ears—that experienced loudness is related logarithmically to wave amplitude.

Third, measurement is a perceptual process—at least it relies on and largely uses perception—so it may be only producing various correlations of *sensa* and never getting through to the supposed properties of material objects at all. This objection is made from the point of view of phenomenalism, however, while the whole primary-secondary quality distinction presupposes representative realism. Supporters of the latter would say that the best explanation of the correlation is that the sense experiences arise in the measurement of actual physical objects.

ARGUMENTS FROM SCIENCE. Science can adequately explain and describe the nature of the physical world solely in terms of primary qualities; hence, while primary qualities must characterize objects, there is no need to suppose that secondary qualities must also. The latter would be otiose, and on the principle of economy, or Ockham's razor (that entities should not be multiplied more than is necessary), it would be unscientific to suppose that they exist as intrinsic properties of objects. The objection to this argument is partly that the science of one's day is not final (thus, Locke was persuaded by seventeenth-century science to include solidity in the list of primary qualities), and mainly that scientific theory and description are not the whole truth—they describe only one aspect of the world, being limited by their quantitative approach and their instruments. Secondary qualities may thus be real properties of matter with biological or aesthetic functions; Ockham's razor oversimplifies the facts pertaining to living things.

Investigation of the causal processes on which perception depends shows that the only variables capable of transmitting information about the properties of external objects are spatiotemporal ones, which are associated with primary qualities. Thus, light waves (energy distributed in space and time) pass from the object to the per-

ipient, but nothing resembling experienced color and sound is transmitted. But the main force of this argument, since it applies to all the senses, is neurological. The nerves from the different sense organs to the brain are all similar, and therefore the only variables are the frequencies of the impulses (which convey the intensity of the stimulus), their different neural pathways, and their different destinations in the brain. Indeed, it seems to be the different destinations that primarily govern the type and quality of the sensation. And although one can conceive of primary qualities being transmitted by spatiotemporal variables, it is difficult to conceive of color, warmth, taste, or smell being so transmitted. (It may be objected that radio and television can transmit color and sound by converting them into electrical impulses for transmission and then reconverting them. But, strictly speaking, what is converted is not color or sound but light waves or sound waves; moreover, the radio or television station must use microphones and cameras to effect the conversion, and there is no evidence of such conversion devices at the objects we see or hear.)

BERKELEY'S CRITICISMS

Berkeley's formidable criticisms of the distinction between primary and secondary qualities have convinced many people. We have mentioned his objection concerning relativity, which, though valid against Locke, can be avoided by restating the distinction on the basis of measurement. He also has nothing to say on the scientific considerations, which were not explicit in Locke. But he did have some further well-known criticisms. First, he stated, "An idea can be like nothing but an idea." In other words, our *sensa*, being private, mental, and directly perceivable, cannot resemble properties of material objects that are public, physical, and not objects of direct awareness. But resemblance is claimed only for primary qualities; and though *sensa* cannot be extended in physical space, it seems reasonable to claim a structural resemblance, a similarity in form, between the spatial relations that they sensibly possess and those attributed to objects by measurement; thus, it can be confirmed by measurement that various relations between the sides of a square *sensum* hold in the object. A similar resemblance seems plausible in the case of motion. There are, however, some underlying difficulties here. In the older representative realism, *sensa* were mental; and since the mind was held to be unextended, they could hardly have spatial relations. But newer versions would allow some sensible or subjective space different from physical space; certainly *sensa* seem spatial, and there seems to be no reason why what is

directly perceivable and what is not should be unable to have a similar form or character.

Second, matter consisting only of primary qualities—for instance, possessing extension but no color, taste, sound or smell—is inconceivable. This objection is beside the point: Admittedly one cannot conceive, in the sense of "imagine" or "picture to oneself" (Berkeley's sense of the word), any such thing, for what we can imagine is limited by past experience and perception. But the range of possible existents need not be confined to this, and there is much in science, particularly in modern physics, that cannot be imagined or pictured.

Bibliography

CLASSICAL WORKS

Anticipations of the distinction are to be found in Democritus, Fragments 9 and 125, in H. Diels and W. Kranz, *Fragmente der Vorsokratiker*; Galileo, *Il saggiaiore* (The Assayer; 1623), in his *Opere*, edited by F. Flora (Milan, 1952), pp. 311–314; René Descartes, *Principles of Philosophy*, Part IV, Nos. 188–203, and *The World or Essay on Light*, Chs. 1–2. Robert Boyle adumbrated the distinction in his *The Origin of Forms and Qualities* (London, 1666), especially the section titled "An Excursion about the Relative Nature of Physical Qualities"; John Locke stated it in his *Essay concerning Human Understanding* (London, 1690), Book II, Ch. 8; Newton's view is best stated in his *Opticks*, Book I, Part II (paperback, New York, 1952, p. 124), but that was not published until 1704. Berkeley's criticisms are in his *Principles of Human Knowledge*, Secs. 9–20. Edwin A. Burtt, *The Metaphysical Foundations of Modern Physical Science* (London: K. Paul, Trench, Trubner, 1925), contains useful discussion of the early versions.

MODERN WORKS

No book is devoted to the distinction, and substantial treatments are rare, but helpful contributions may be found in the following:

A more recent scientific comment on the distinction is Russell Brain, *Mind, Perception and Science* (Oxford: Blackwell, 1951). L. Susan Stebbing, *Philosophy and the Physicists* (London: Methuen, 1937), attacks scientific versions of it, especially those of Newton and of Arthur S. Eddington (see his *The Nature of the Physical World*, Cambridge, U.K.: Cambridge University Press, 1928).

Among the general works available are Charlie Dunbar Broad, *Scientific Thought* (London: Kegan Paul, 1923) and *The Mind and Its Place in Nature* (London: Kegan Paul, 1925); William Pepperell Montague, *The Ways of Knowing* (London: Allen and Unwin, 1925); Roderick Chisholm, *Perceiving: A Philosophical Study* (Ithaca, NY: Cornell University Press, 1957); and more fully, R. J. Hirst, *The*

Problems of Perception (London: Allen and Unwin, 1959). D. M. Armstrong, *Perception and the Physical World* (New York: Humanities Press, 1961), Chs. 14 and 15, discusses the subject from a direct realist position, and Gilbert Ryle's criticisms of the distinction in his *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954) are well known.

Among articles on the distinction are Reginald Jackson, "Locke's Distinction between Primary and Secondary Qualities," in *Mind* 38 (149) (1929): 56–76; J. J. C. Smart, "Colours," in *Philosophy* 36 (137) (1961): 128–142 (reprinted with additions in his *Philosophy and Scientific Realism*, New York: Humanities Press, 1963); Colin Strang, "The Perception of Heat," in *PAS* 61 (1960–1961): 239–252; and for a more general treatment, W. C. Kneale, "Sensation and the Physical World," in *Philosophical Quarterly* 1 (2) (1951): 109–126.

R. J. Hirst (1967)

Bibliography updated by Benjamin Fiedor (2005)

PRINGLE-PATTISON, ANDREW SETH (1856–1931)

Andrew Seth Pringle-Pattison, the Scottish personal idealist, was born Andrew Seth, in Edinburgh. (He adopted the surname Pringle-Pattison at the age of forty-two as a

condition of inheriting a family estate in Scotland.) He studied philosophy at Edinburgh University under Campbell Fraser. Two years of study in Germany convinced him that it was the worst place for the study of German idealism but resulted in his completing, at twenty-four, his Hibbert essay, *The Development from Kant to Hegel*. From 1880 to 1883 he served as Fraser's assistant at Edinburgh and then took the foundation chair of philosophy in the University College of South Wales at Cardiff. He left Cardiff in 1889 for the chair of logic and metaphysics at the University of St. Andrews. This he relinquished in 1891, when he succeeded Fraser at Edinburgh. In 1919 he resigned, after thirty-nine influential years as a university teacher.

Philosophy for Pringle-Pattison was a serious enterprise of the human spirit, which he did not distinguish strictly from a statement of his own findings in religion and morality. His writing is clear and eloquent but not very original. He sought to advance his subject through critical interpretation of the great philosophers, especially Immanuel Kant and G. W. F. Hegel. He was skeptical about the value of philosophical systems, holding that we cannot know the universe as we can know its individual parts; only God can do this. Rather, "the ultimate harmony may justifiably be spoken of as an object of faith—something which I am constrained to believe, even though I do not fully see it."

Pringle-Pattison was a Scottish Hegelian with a difference. Rebellious against the absolutism of Hegel and of such Hegelians as Francis Herbert Bradley and Bernard Bosanquet, for whom the individual is merged in the universal, he insisted on the uniqueness of the individual person. It is only as knower that the self is a unifying principle. As a real being it is separate and distinct, impervious to other selves, even to God. "I have a centre of my own—a will of my own—a centre which I maintain even in my dealings with God Himself." We feel this to be so; it neither needs to nor can be established by argument. But God too is a Person; we cannot deny him self-consciousness, because this is the highest source of worth in ourselves. Hegel and the Hegelians were at fault here also.

Philosophy, Pringle-Pattison held, cannot do justice to "the individual within the individual—those memories, thoughts, and feelings which make each of us a separate soul" (*Hegelianism and Personality*, p. 217). Religion and poetry go further and deeper than philosophy, and this, as he said, is why he drew so frequently on the poets.

Our knowledge of the Absolute starts from experience—our experience "of the concrete worlds of morality, of beauty, of love or of the passion of the intellectual life."

It is, however, a postulate of reason that the world is a cosmos, not a chaos, which we can gradually explore but never grasp in its entirety. Pringle-Pattison described his philosophy as “a larger idealism” that reconciles the dictates of morality and religion with the findings of science, purpose being the supreme category.

He was cautious in his claims about immortality. The nature of the soul is such that it is reasonable to entertain the hypothesis of its survival, and since human spirits must be “values for God” they were surely not made to be constantly destroyed and replaced by others. Yet if there is personal immortality, it is not the inherent possession of every human soul but must be won by the continuous effort needed to develop a coherent self. Morality does not depend on personal immortality, nor need immortality be the central article of philosophy or religion. In the apprehension of Truth, Beauty, and Goodness—eternal realities—man has already tasted eternal life and so should not be much concerned about personal survival.

A. K. Stout (1967)

PRIOR, ARTHUR NORMAN (1914–1969)

Arthur Norman Prior was born on December 4 at Masterton, near Wellington, New Zealand. He acknowledged an early philosophical debt to John Findlay. But his first academic post was at Canterbury University College, where he succeeded Karl Popper. He was the visiting John Locke Lecturer at Oxford in 1956, and in 1958 he was appointed a professor of philosophy at the University of

Manchester. After short periods as a visiting professor at the University of Chicago and at the University of California at Los Angeles, he moved in 1966 to a tutorial fellowship at Balliol College, Oxford, and Oxford University appointed him to a concurrent readership.

Prior's early intellectual interests were very much religious in character. He was influenced for several years by the theologian Arthur Miller, who combined a strict adherence to Presbyterian doctrine with an equally strong support for socialism and opposition to nationalism. But Prior's pacifism weakened, and he served from 1942 to 1945 in the New Zealand air force. And the central focus of his interests gradually shifted—helped by an occasional bout of atheism—from theology to ethics and logic. He exchanged ideas with a wide circle of friends and acquaintances, and his hospitality to students was legendary.

Prior's first book, *Logic and the Basis of Ethics* (1949) traced seventeenth-, eighteenth-, and nineteenth-century anticipations of G. E. Moore's criticism of the so-called naturalistic fallacy. But his main claim to fame lies in his pioneering work on the formal logic of temporal relationships. His most important investigations in this field were published in *Time and Modality* (1957), *Past, Present, and Future* (1967), and *Papers on Time and Tense* (1968). But he also wrote on several logical topics in this encyclopedia; he published a substantial survey of the current state of logical inquiry under the title of *Formal Logic* (1955; 2nd ed., 1962); and a posthumous volume of papers, *Objects of Thought* (1971), was edited by P. T. Geach and A. J. P. Kenny.

Prior almost always used the Polish style of notation in the discussion of logical proofs and principles and was a convinced, though largely unsuccessful, champion of its virtues. The major inadequacy in his tense logic, however, was a failure to discuss or accommodate aspectual differences—roughly, differences between the meanings expressed by verbs in a perfect tense and those expressed by verbs in an imperfect tense (see Galton, 1984). Other criticisms may be found in L. J. Cohen's (1958) review of *Time and Modality* and in his subsequent controversy with Prior (*Philosophy* 34 [1959]). In his *Formal Logic* Prior displayed an impressively wide acquaintance with logical systems outside the field of tense logic, and this book remains a useful text for anyone interested in comparisons between different axiomatizations of the propositional calculus, between different kinds of logical quantification, between different modal logics, or between different three-valued or institutionist logics. But the treatment of metalogical issues in the book is

occasionally rather selective: for example, in its discussion of completeness proofs for the predicate calculus as against its treatment of completeness proofs for the propositional calculus.

Outside the brilliant originality of his work on tense logic, perhaps Prior's most striking idea was expressed in "The Runabout Inference-Ticket" (1960), where he argued that, if the meaning of a logical connective consisted just in the logical uses to which it can be put (as many seemed to hold), then it would be easy to invent a connective with a meaning that would enable one to infer any conclusion from any premises.

PRIVATE LANGUAGE PROBLEM

The private language problem is essentially the question of whether or not a language as a system of symbols that

are means of thinking is, of necessity, a language as a system of symbols that are means of communication. Defining "private language" as language (in the sense of means of thinking) which in principle the speaker alone can understand (so that it cannot serve as a means of communication), our question is roughly equivalent to: "Is a private language possible?" Many philosophers, following Ludwig Wittgenstein, have made the claim (here called the private language thesis, abbreviated PLT) that private languages are impossible. Armed with it, they have argued against solipsism, phenomenism, the analogical or empirical view of one's knowledge of other minds, and against mind-body dualism. Some of them have gone on to argue for certain versions of philosophical behaviorism as well as for the view that the meaning of a word consists of its use or employment in a social practice and not in its referring to something or its designating a kind of entity.

Thus, the PLT has been a central principle in the cluster of Wittgensteinian doctrines. It is not clear, however, that exactly the same thesis figures in all the arguments in question, since the idea of a private language varies in different contexts. There is, therefore, a multiple problem: First, to differentiate the several propositions which pass as the PLT by clarifying the sense of "private language" being used; second, to determine which ones are true; and third, to explain why they are supposed to be intimately related. These problems differ from the question, debated around 1930, of whether or not it is possible to start with a private language about one's sensations or "raw" feelings and arrive at the intersubjective and communicable language of science. (On this question, see Rudolf Carnap, "Psychology in Physical Language," and J. R. Weinberg, *An Examination of Logical Positivism*.)

THE SENSE OF "IMPOSSIBLE"

In all the interpretations of the PLT, the word *impossible* is understood in a strong sense that is not easy to characterize precisely. Some philosophers speak of "logical impossibility," but they do not necessarily mean that private languages are impossible in the sense that unbounded triangular figures are impossible. The expression "unbounded triangular figure" reduces to the formal self-contradiction "*unbounded* figures *bounded* by three lines" by means of a substitution allowed by the definition of "triangle." But few philosophers would suggest that there is a similarly ready definition of "language" by means of which we can produce a formal self-contradiction "private so-and-so which is not private." The impossibility at issue is like (1) the impossibility of unextended red things (that is, the impossibility that something be red and yet lack

width or length), or (2) the impossibility of a cube with fewer than eight edges. These do not lead straightforwardly to formal contradictions, since there are no definitions for all the terms involved; they depend on implication relations that constitute the concepts involved in their statement. In the last analysis, the persistent rejection of (1) and (2) evidences the failure to understand the meanings of all the words involved, that is, the lack of some of the relevant concepts. But (1) is unprovable and obvious, and (2) only needs a trivial argument, while the PLT (if true) requires careful reasoning. We shall speak of *conceptual impossibility* to refer to any formal self-contradiction, to any impossibility which entails a formal self-contradiction, and to any a priori impossibility such as that found in the above examples (1) and (2).

THE PRIVATE LANGUAGE THESIS

The most important propositions often discussed as the PLT, each embodying a different idea of private language, are the following:

PLT*: It is impossible for a man to use a word with a meaning that nobody else could, even in principle, understand.

PLT-1: It is impossible for a man to use words that refer to private objects, that is, objects that nobody else could—even in principle—know. (For subtheses arising out of the ambiguities of “know,” see H.-N. Castañeda, “The Private-Language Argument.”)

PLT-2: It is impossible for a man who has always lived in isolation to possess a language, even if his sounds are understandable by another person.

Here the expressions “could not in principle” and “impossible” are meant to express conceptual impossibility. PLT* allows that a man may use words with meanings that nobody else in fact understands, provided that they are understandable to other people in the appropriate circumstances. PLT-1 allows that a man may refer to objects that, in fact, he alone knows, but again others must be capable of knowing them in the appropriate circumstances. PLT-2 allows that a man, like Robinson Crusoe, keeps possession of a language he learned previously while living in a community of speakers.

Many philosophers assume that it is conceptually impossible for two persons to share one and the same immediate sensation. Many also hold that, in a strict sense of “know,” others do not really know whether one has a certain immediate sensation or not, precisely because they cannot share it. On these assumptions, a language about one’s own immediate sensations would be

a language of the sort that PLT-1 claims to be impossible. Indeed, such a language is customarily regarded as the would-be prototype of private language.

In general, on the assumption that (direct) knowledge of the referent of a word is required for understanding the meaning of the word in question, PLT* entails PLT-1. On this assumption, a language about one’s own immediate sensations is also private in the way that PLT* claims to be impossible.

PLT-1 does not entail PLT*. A word might have a meaning understandable to only one person because the word itself is a private object in the sense of PLT-1, even though everybody may be acquainted with the physical objects it refers to. For example, the words of a person’s language might all be mental images of German written words, so that all his thinking would be a sort of mental reading of German. In this case, the referents of the words would be public, but the words themselves would be private and hence unintelligible to others.

PLT-2 neither entails nor is entailed by PLT-1. If PLT-2 is true, then if on the previous assumptions about sensations, one’s language about one’s own sensations is private in the sense of PLT-1, then one could still, in principle, invent such a language. Conversely, the truth of PLT-1 does not by itself make it impossible for an isolated person to invent a language about physical objects. Similarly, PLT-2 neither entails nor is entailed by PLT*.

APPLICATIONS OF PRIVATE LANGUAGE THESES. The important claims made with the help of the PLT do require other assumptions, which in their turn play roles, as we shall see, in the defense of the PLT itself. The most natural and pervasive of these assumptions is the following:

(A) In the sense of “thinking” in which one can both have a false (or true) thought and draw inferences from what one thinks, it is conceptually impossible to think without possessing a language that is a means of thinking.

From this assumption and PLT-2, one can conclude that the fact that one thinks, guarantees the existence of other persons, namely, one’s fellow speakers of the same language. Thus, the solipsist who merely asserted that it is possible that he alone exists at the time he is thinking would be contradicting himself (an argument of this sort can be constructed with premises suggested by Rush Rhees in “Can There Be a Private Language?”). Of course, many philosophers have serious objections to (A).

The existence of hallucinations, illusions, and visual perspective leads many philosophers to characterize every

case of perception in terms of our apprehension of sense data or immediate impressions. Some have proceeded to espouse a phenomenalist program of “logical reconstruction” of physical objects and minds as systems of sense data; others, however, have subscribed to some form of realism, that is, the complete irreducibility of physical objects and minds to sense data. But all of them have recently been criticized on the ground that the language of sense data is private in either the sense of PLT* or the sense of PLT-1. Here, in addition to (A), the critics need the following assumption:

(B) If it is conceptually impossible that there be a language about entities of a sort *T*, then there are no entities of sort *T*.

Again, some philosophers would claim against (B) that if PLT* or PLT-1 is true, then sense data or the given in experience are simply ineffable.

Many philosophers have subscribed to some form or other of a principle of verification, for example:

(C) It is conceptually impossible to understand a sentence without knowing what state of affairs would verify the statement made with it.

Assumption (C) leads to the view that language about states of consciousness is private, if we add to it and (A) and (B) the following principle:

(P) Only the person himself can verify conclusively and directly that he has certain experiences.

On this view, for instance, when someone else speaking about me says, “He is in pain,” he cannot understand or mean exactly the same thing that I understand and mean when, of myself, I say, “I am in pain.” But if PLT* is accepted, one is involved in a contradiction. Here many philosophers have given up (P), and in order to guarantee that everybody else can know what somebody is feeling or thinking, some philosophers have espoused some form of behaviorism, that is, a view according to which every description of a person’s experiences or mental states is really shorthand for (synonymous with) a description of his bodily movements, his relations to other bodies, and his abilities to perform further movement. This is often supplemented with the supposition that first-person utterances like “I have a headache” do not make statements of direct knowledge but are, rather, learned responses, analogous to the natural responses of moaning, crying, and so on, which are said to constitute the person’s ache. As is to be expected, other philosophers have preferred to keep (P) and reject one or more of the other premises, in particular (C) or PLT*. (See Castañeda,

op. cit., Part B, for a discussion of the privacy of experiences.)

THE MAIN ARGUMENTS FOR THE PLT. There are many arguments seeking to prove that being private makes it impossible for a language to have a property required for the existence of a language. Most of the arguments depend on the following assumption:

(D) A language is a system of rules, and to speak or write a language is to follow rules.

On this assumption, it suffices to establish the PLT to show that a man (say, Privatus) cannot be following rules when he is using a private language (to be called Privatish). This is, in fact, what a series of arguments suggested by Wittgenstein purports to do. The gist of the argument is as follows: A rule is, by its very nature, the sort of thing that can be misapplied (or disobeyed), but Privatus cannot misapply the rules of Privatish; hence, when speaking Privatish, Privatus is not following rules. The specific arguments are meant to support the crucial premise:

(1) Privatus cannot misapply the rules of Privatish.

A fair objection to (1) is that Privatus can certainly make slips; he may call something of kind *A* “*B*,” whatever “*A*” and “*B*” may mean in Privatish. Slips of the tongue are precisely ways in which one violates the rules (if there are such) of natural languages. For instance, if there are rules of English governing the application of color words to physical objects; whenever one commits a slip of the tongue and calls a red object “blue,” then one misapplies either a rule governing the use of “red” or one governing the use of “blue.”

This reply to (1) is often met by several rejoinders. The first claims both that a slip counts as a misapplication of a linguistic rule only if there is a way in which the speaker can in principle detect and correct his slip and that Privatus cannot detect or correct his slips. This rejoinder, however, changes the issue, since premise (1) says nothing about verifying the existence of a misapplication of a rule. Nevertheless, the rejoinder has a point, for if to use words is to apply rules, then one must at least sometimes be able both to know of one’s misapplications of the rules for the use of one’s words and to know how to make the appropriate corrections. The question of whether or not Privatish allows this is discussed below under premise (2).

The second rejoinder is that to obey a rule is a *custom* (use, institution), but Privatus’s actions cannot constitute a custom (see Ludwig Wittgenstein, *Philosophical Investi-*

gations, Sec. 199). This rejoinder would establish PLT-2 but not PLT* or PLT-1. For it may be a custom in a tribe that people use words which they alone understand in the ways required by PLT* or PLT-1. But as an argument for PLT-2 the rejoinder is by itself question-begging. It must be supported by an argument which shows that obeying a rule is indeed a custom.

The third rejoinder is that Privatus's slips do not count as violations of the rules of Privatish because we cannot be corrected or taught by others what is the correct thing to say (see Wittgenstein, *op. cit.*, Sec. 378, and Norman Malcolm, "Discussion of Wittgenstein's *Philosophical Investigations*," pp. 536f.). If the "cannot" here is taken to mean conceptual impossibility, the rejoinder does not apply to PLT-2. If it is taken in a weaker sense, that is, a sense in which a person may be in the position of being in fact corrected by other persons, then the rejoinder supports PLT-2, but it would not allow that there be just one language-user in the universe. Besides, it is not clear that it would allow that Antonia Udina, for example, used language when, as we normally say, he spoke Dalmatian as the last speaker of Dalmatian. Although a person who uses words must be capable of self-correction, it is not immediately obvious that a person's sounds cannot count as utterances of words if nobody else can (in some sense) correct him. The need for others' possible corrections has to be established by an argument. Thus, we are again thrown back to the other lines of reasoning.

The fourth rejoinder is that Privatus's slips do not count because another person, by noting Privatus's behavior and circumstances, cannot discover that his use of the word is correct or incorrect (adopting Malcolm, *op. cit.*, p. 537). This rejoinder also leaves PLT-2 unsupported if "cannot" is understood as expressing conceptual impossibility. While it must be conceptually possible for Privatus to know whether his uses of language are correct or incorrect, it is not at all clear that it must be possible for others to know this fact. The principle that it must be possible for others to know whether his uses of language are correct or incorrect requires an independent argument to support it. However, the present rejoinder has a point. It reminds us that if there is no way at all of telling, for any word of Privatish, whether or not Privatus used it correctly (however coherent the concept of a private language is), it would be a completely gratuitous hypothesis that Privatus spoke a private language. Although our topic here is only the conceptual possibility of private language, we should note that the claim that somebody's entire language is of the type described in PLT* is cer-

tainly gratuitous. Yet the claim that someone has a mixed language, part of which is private in the sense of PLT*, does not seem gratuitous.

The fifth rejoinder dismisses mere slips on the ground that they show at most a breakdown of a linguistic habit. The rejoinder asks us to consider the case of Privatus trying deliberately to apply a rule of Privatish and failing to comply with it. The rejoinder claims that, for Privatish, "thinking one was obeying a rule would be the same thing as obeying it," but "to *think* one is obeying a rule is not to obey a rule. Hence it is not possible to obey a rule 'privately'" (Wittgenstein, *op. cit.*, Sec. 202). This rejoinder does not require that every utterance of a word be a case of deliberately attempting to obey the corresponding linguistic rule(s). Conjoined with assumption (A), this view would lead to a vicious infinite regress. For then, in order to say something, one would have to be aware of the rules governing the words one intends to utter, and these rules in their turn would be formulated in some words the rules governing which one would have to be aware of through some other words, and so on ad infinitum. Therefore, to use language is, of necessity, to use most of the words from habit, not in intended obedience of the linguistic rules. The rejoinder cannot even demand that Privatus sometimes be aware of the rules of Privatish: A being might speak a language without ever rising to the level of formulating any of his rules. But if, by assumption (D), languages are made up of rules, then if it were conceptually impossible for Privatus to be at least sometimes aware of the rules of Privatish, Privatish would be a very defective language indeed, incapable of discharging the philosophical duties that private languages are alleged to discharge. Thus, the rejoinder is right in urging that

(a) For every rule R of a language L and every speaker S of L , it is conceptually possible that sometimes R applies to S 's situation while S thinks that he is obeying R without S 's actually obeying R .

Presumably, a rule of language is here of the form "If x is ϕ , you may (must) call it '...,'" but the meaning of "call" is difficult. In one normal sense of "call," slips of the tongue are, again, ways in which (a) is true. Clearly, a person may think that he is calling a thing "red" in deliberate compliance with the English rule for "red," without realizing that he actually called it "blue" because he is deaf or because he simply did not hear what he said. In the same sense of "call," (a) can be true because the speaker deliberately calls a red thing "blue," if he thinks that the rule in question allows (or prescribes) his calling it "blue." In particular, suppose that the rule R allowing (or prescrib-

ing) that one call a thing “red” is the rule Gaskon typed yesterday and that today, confusedly, Gaskon thinks that the rule he typed yesterday allows (or prescribes) that a certain thing be called “blue,” and he calls the thing in question “blue,” thinking that he is complying with the rule. Here, in spite of his deliberately calling a certain thing “blue,” Gaskon’s use of “blue” and the rule he thinks he is complying with both satisfy (a). Both ways of satisfying (a) are open to Privatus. It might be argued that Privatus’s deliberately calling one of his private objects “A” instead of “B” has no point or “function” (see Wittgenstein, *op. cit.*, Sec. 260), since he is not talking to others. This is, however, false. Privatus may very well play word games involving miscallings of things. But more importantly, whether or not there is a point in Privatus’s flouting of the rules of Privatish has nothing to do with the issue about the possibility of private language.

The rejoinder often uses a stronger sense of “call.” In this sense, by a natural development of assumption (A), to *think* that something is, for example, red is to call it “red.” This stronger sense appears in an argument given in support of PLT-1. As said above, language about one’s own immediate sensations is often regarded as the paradigm of private language in the sense of PLT-1. Now, one knows incorrigibly that one’s sensations have immediately sensible qualities. That is to say, if one believes that one has a pain (itch, tickling, feeling of discomfort), then one knows that one has a pain (itch, tickling, feeling of discomfort). So it is impossible to have no pain while one thinks that one has a pain. Thus, if one thinks that one is obeying the rule of the form “If x is a pain, you may (must) call it ‘pain,’” one surely thinks that one is in pain and the rule cannot fail to apply. Similarly, since one also has incorrigible knowledge of the absence of one’s immediate sensations, if the objects that Privatus can think about in Privatish are only his immediate sensations, then when he thinks that a rule of Privatish does not apply, the rule does not, in fact, apply. But if “call” is taken in its normal sense, neither of these two features of the rules of Privatish implies that Privatus cannot think that he is obeying a rule (which then applies) without actually obeying it, since slips and deliberate miscallings are still available as violations of the rule. However, if “call” is taken in the strong sense (in which thinking can be calling), then if Privatus thinks that he is obeying a rule of the form “If x is A , you may (must) call it ‘A,’” he surely thinks that the rule applies, that is, he thinks that the object x is A ; if A is a sensible property of Privatus’s immediate sensation x , then x is A , and Privatus is both calling x “A” and unavoidably obeying the rule. Thus, if Privatish is a private language about Privatus’s immediate

sensations and their sensible properties, then (a) above and (b) below are both false:

(b) For every rule R of a language L and every speaker S of L , it is possible that sometimes S thinks that he is obeying R while he is not.

Since (a) is true, Privatish is not a private language.

This argument does not by itself support PLT-2; it may or may not support PLT*, depending on how one interprets the phrase “knowing the meaning of a word.”

There is, however, a difficulty with the above argument. Consider the rule of English: “If x is a cat, you may (must) call x ‘cat’; that is, you may (must) think that x is a cat.” This rule differs from the above rule for the Privatish word “A” in that thinking that one is obeying the rule for “cat” does not imply that the rule for “cat” applies to the situation in question. For to think that one is obeying the latter rule implies that one thinks that it applies, and this implies that one thinks that some object x is a cat. But surely one can be mistaken about x ’s being a cat. Yet the rule for “cat” also fails to satisfy condition (a). Suppose that the rule applies; then the object x in question is a cat. And suppose that one thinks that one is obeying the rule; then it is true that one thinks that if x is a cat one may (must) think that x is a cat, and that one thinks that x is cat. Thus, one is in fact obeying the rule! Therefore, the strong sense of “call” included in the concept of language rule R makes (a) an impossible condition.

Now, in the case in which a rule R does not apply to a man’s situation, we are often reluctant to say that when such a man thinks that he is obeying R , he is not obeying R . But we could say this with no great distortion, and if we did, we could say that the above rule for the English word “cat” satisfies condition (b). For in a situation in which an object x is not a cat and the rule does not apply, we may very well both misperceive or otherwise think that x is a cat and think that, in accordance with the rule, we may (must) think that x is a cat. Thus, if we raise (b) as the crucial condition that linguistic rules must satisfy, then we can claim that PLT-1 is established in the sense that a pure language of sensations is impossible. But this answer is inconclusive. Besides the small amount of distortion involved, there is the fact that (b) is not a general condition of rules. This is shown by the following rule which a man might give to his son: “If you think that you need to delay your action, think that $1 + 2 + 3 + \dots + 24 = 300$.” Since to think that one thinks that p entails that one thinks that p , if the boy thinks that the rule applies, he thinks he needs to delay his action, and the rule applies. If he thinks that he is obeying the rule, he thinks

both that it applies and that $1 + 2 + 3 + \dots + 24 = 300$; hence he thinks that $1 + 2 + \dots + 24 = 300$; hence, the rule applies and he obeys it. Thus, to defend PLT-1 by means of (b) requires an independent argument showing that rules of language must, in any case, comply with (b), distorted as suggested.

Let us turn now to a subtler line of argument. Some defenders of the PLT do not argue for (1) but for

(2) Privatus cannot distinguish his correct uses of Privatish words from his incorrect uses.

Suppose, then, that Privatus is debating whether something is *A* or not. Suppose that Privatish is private in the sense of PLT-1. Here the defenders of the PLT adduce (a) that Privatus lacks a *criterion* of correctness, that is, “something *independent* of his impression” that he is correctly using the Privatish rule governing the use of “*A*” by means of which he can “prove his impression correct” (Malcolm, *op. cit.*, p. 532), and (b) that his impression that he remembers what objects of kind *A* appeared like before is of no help, since memory “is not the highest court of appeal” (Wittgenstein, Sec. 56) and the “process [of checking memories] has got to produce a memory which is actually *correct*” (Sec. 265). Now, these points exaggerate Privatus’s predicament. Privatus’s private objects may be related among themselves by entailment, by coexistence, by similarities, by causal relationships, and so on. Privatus can resort to any of these to test whether he is, on the present occasion, using the term “*A*” correctly. For instance, in Privatish, “being *A*” may be logically equivalent to “being *B* and becoming *C* in the presence of another *C*.” Indeed, Privatus may even employ paradigms. The very first object he calls “*A*” may very well be enduring, so that he can compare the next objects of kind *A* with it. The same applies to languages of the type mentioned in PLT-2. Furthermore, memory is the highest court of appeal when it comes to our knowledge of the past. True, we have records and other historical evidence, but all of this only provides inductive evidence, not a proof, and our inductions involve the acceptance of unchallenged memories.

Nevertheless, Privatus is not only in no position to question the correctness of all of his uses of words, but he also cannot *prove* that the uses he questions are correct unless he is allowed the ability to identify certain properties of objects without criteria and without challenging his memory. But exactly the same happens with the speakers of *any* language. In the case of terms like “red” and “straight,” for instance, there is nothing at all to which an English speaker *E* can resort in order to “prove” that he has correctly called an object red or straight. His

fellow speakers may all utter in unison, “Not red but blue.” Yet this choral utterance is not a proof; the speakers may be lying, may all be victims of a hallucination, or may just be rehearsing a new song—or the whole proceedings may be just *E*’s hallucination. In any case, for *E* to accept the correction, he must correctly identify the words expressing it without the use of criteria and remember correctly the meanings of these words. A vicious infinite regress would ensue if *E* were required to have a proof that he both remembers this correctly and identifies the objects the words apply to.

Moreover, there is nothing to prove each corrector’s use of words correct. Suppose, for example, that one corrector learned the meaning of “blue” with the help of object *O* and that he continuously stares at *O* during the preceding two minutes before correcting Privatus. He still must *remember* correctly that *O* has the same color it had two minutes before, that the color of *O* is called “blue,” that the name of the color sounds “b–l–u–e,” that the noise “red” uttered by *E* has the same meaning that makes red and blue incompatible, and so on. Thus, either somebody *just* identifies some words or objects correctly and remembers some qualities of objects and the meanings of some words correctly, or else nobody can be corrected by another speaker. In sum, demands (a) and (b) cannot be adduced against the possibility of a private language.

LOGICAL WORDS. Often it is claimed that a private language cannot have logical words or syntactical rules, both of which are necessary for the existence of logical relationships. Clearly, if a private language is allowed no implications or entailments, it would certainly be no language. But if “private language” is meant in the sense of PLT* or PLT-1 or PLT-2, this contention appears to be false. Often this contention is defended on the ground that a really private language does not have words with meanings in common with the words of another language (Wittgenstein Sec. 261; Malcolm p. 537). Now, private language in this sense is impossible. A language is a system of words of which some refer to objects, some signify properties or relations, and some express logical connections; the words expressing logical connections must be capable of being understood by anybody else and must, therefore, be common to all languages. This is an important result. But it is not the same as PLT*, which requires that every single word of a language must be understood by persons other than the speaker. Likewise, the impossibility of languages without logical words does not imply that a language cannot have some nonlogical words which refer to private objects, that is, it does not imply that PLT-1 is true. Again, that a language must have

logical words implies nothing about the possibility of a single man developing a language for and by himself, that is, does not imply that PLT-2 is true.

“THE SAME.” Apparently Wittgenstein knew that there are no criteria (in the sense of something independent) which prove that words have been used incorrectly. He also knew that the correctness of an application of a word is not determined by a rule whose formulation serves as a recipe or canon. His fundamental opposition to private language derives from his profound investigations into the nature of concepts and his strong inclination toward an extreme nominalism. This opposition is never crystallized in a definite argument, but its gist is, in crude form, as follows. Postulate:

(E) The similarities and samenesses we find in things do not exist *in rerum natura*, that is, do not exist in things as we find them, independently of our finding them or of our referring to them in the way we do; they “come from the language” (Rhees p. 80) and at bottom consist of the fact that we “call” the things in question the same (Wittgenstein Secs. 146, 149, 185–190, 208–223, 348–352).

On a rigorous interpretation of (E), we find a rationale for assumptions (A), (B), and (C), as well as for the fact that the PLT has a chameleon-like and pervasive character. If we take (E) literally, then to find a property in several things is to find that we “call” the things in question “the same” or refer to them with the same word. Thus, it is impossible to think that something is such-and-such without a language in which there is an expression (even if a very long phrase) which “constitutes” the such-and-such in question. This is assumption (A). Also, (B), without an expression “constituting” a type *T*, there is no type *T* for things to belong to. Similarly, to understand an expression is not to apprehend an independently existing (or subsisting) property but simply to know how and to what to apply it, and this includes knowing how to call certain utterances “true” in which the expression is correctly applied. This is, in fact, a generalization of assumption (C).

We cannot say that a man in doubt about whether or not he used a word correctly must simply identify certain features of things without criteria and, armed with these identifications, test his uses of words. For on the extreme interpretation of assumptions (A) through (E) to identify a feature is to “call” a thing something. So, when the use of a word is at issue, the identification and nature of the thing is precisely what is at issue. The referents of one’s previous uses of the word, as well as the uses themselves, are irrelevant. If one “calls” something “A,” then it is A

and *a fortiori* similar to the previous A’s; if one withholds the name “A” from it, then it is not an A, and a fortiori it is dissimilar to all A’s with respect to being an A. Clearly, it does not matter whether one’s language is about private or about public objects; one’s uses of words simply fail to be capable of being incorrect. They would seize reality so well that each “would have to be at once a statement and a definition” (Rhees p. 82).

Thus, the following question arises. If, on assumption (D), language is a matter of rules and rules are the sort of thing that can be misapplied or not, how, then, is language possible after all? At this stage, obviously, we are not interested in proving anything but are anxious to find an explanation. Wittgenstein seems to suggest one: A man’s uses of words can be incorrect only if they are compared with those of his fellow speakers. His “calling” something “A” is correct if his cospeakers now also call it “A.” Then it is A and a fortiori similar to the things he and his cospeakers previously called “A.” That is why obeying a rule of language is a practice (Wittgenstein, op. cit., Sec. 202). It is not necessary that the speakers of the language should call the thing in question “A” or that they call it “A” afterward. Nor is it necessary that they call it “A” or anything at all, or that they call it the same thing. It is just a contingent fact that they coincide in calling it “A.” But this coincidence (or agreement) is an empirical fact that is necessary for the existence of language.

Such is the underlying argument of Wittgenstein’s remarks (Secs. 146, 149, 185–190, 208–223; for a discussion of the role of Wittgenstein’s extreme nominalism in his views about necessary truth, see Michael Dummett’s “Wittgenstein’s Philosophy of Mathematics”). He builds a Heraclitean picture of language as something living only in our actual use of it and changing according to our needs. But is this a true picture of the connection between language and reality?

Here we cannot discuss the whole issue of nominalism, but to this writer it seems indefensible. We could doubtless have classified objects in entirely different ways from the ways we in fact do. For instance, we might have had no color words, no terms for species of plants or animals, and instead have used, say, “sha” for some elephants and white roses and reddish sand, and “sho” for female elephants, eggs, and rivers. But even so, we should have had to *find* features of similarity in the things so classified, and these features would have provided tests for the correct application of our words. At any rate, the view that things are the same because we “call” them “the same” or because we refer to them with the same words can get off the ground only by postulating our recogni-

tion of the samenesses of words, that is, the similarities of noises whose application to things constitutes the similarities of the latter. A serious infinite regress would ensue if we also hold that our words are similar only because we “call” them so.

The several propositions that are often debated as the claim that private languages are impossible can be linked to each other only under the assumption of extreme nominalism. None of the arguments given for the claim appear to be successful. There may be no conclusive way of either proving or refuting this claim. Perhaps the only course is to build detailed and rigorous philosophical views on each alternative and assess the adequacy of such views by their consequences. This topic continues to be widely discussed in the literature, and many philosophers adopt a position different from that advocated in the present article.

THE PROBLEM BEFORE WITTGENSTEIN

Carnap, Rudolf. “Psychology in Physical Language.” In *Logical Positivism*, edited by A. J. Ayer. Glencoe, IL: Free Press, 1959. Ch. 8. Translated by Frederic (there called George) Schick from the German version, which appeared in *Erkenntnis* 3 (1932–1933).

Weinberg, J. R. *An Examination of Logical Positivism*. New York and London, 1936. Ch. 11.

WITTGENSTEIN’S VIEWS

Albritton, Rogers. “On Wittgenstein’s Use of the Term ‘Criterion.’” *Journal of Philosophy* 56 (1959): 845–857. An excellent collation and exegesis of the passages in which Wittgenstein discusses criteria; brings out certain internal tensions in Wittgenstein’s conception.

Dummett, Michael. “Wittgenstein’s Philosophy of Mathematics.” *Philosophical Review* 68 (1959): 324–348.

Malcolm, Norman. “Wittgenstein’s *Philosophical Investigations*.” *Philosophical Review* 63 (1954): 530–559. An extended review and discussion that presents Wittgenstein’s arguments against the PLT, with emphasis on the private language speaker’s lack of a criterion of correctness.

Rhees, Rush. “Can There Be a Private Language?” *PAS*, Supp., 28 (1954): 77–94. A symposium with A. J. Ayer containing an exposition of Wittgenstein’s views on private language understood mainly as PLT-2; conveys Wittgenstein’s nominalistic rationale very well, without discussing it as such.

Wittgenstein, Ludwig. *Philosophical Investigations*. German with facing translation by G. E. M. Anscombe. Oxford: Blackwell, 1953.

THE PROBLEM AFTER WITTGENSTEIN

Ayer, A. J. “Can There Be a Private Language?” *PAS*, Supp., 28 (1954): 63–76. A symposium with Rush Rhees in which Ayer criticizes the PLT and emphasizes the need for criterionless identification at some point.

Carney, James. “Private Language.” *Mind* 64 (1960): 560–565. Favors the PLT.

Castañeda, Héctor-Neri. “Criteria, Analogy, and Knowledge of Other Minds.” *Journal of Philosophy* 59 (1962): 533–546. Discusses some problems of Malcolm’s views on criteria.

Castañeda, Héctor-Neri. “The Private-Language Argument.” In *Knowledge and Experience*, edited by C. D. Rollins. 1962 Oberlin Philosophy Colloquium. Pittsburgh: University of Pittsburgh Press, 1963. A symposium with V. C. Chappell and J. F. Thomson; surveys critically the arguments for the PLT and also replies to the other symposiasts.

Chappell, V. C. “Comments.” In *Knowledge and Experience*, edited by C. D. Rollins. Vigorously defends the PLT from criticisms raised by Castañeda’s discussion.

Garver, Newton. “Wittgenstein on Private Language.” *Philosophy and Phenomenological Research* 20 (1960): 389–396. Favors the PLT.

Hardin, Clyde L. “Wittgenstein on Private Language.” *Journal of Philosophy* 56 (1959): 517–528. Attacks the PLT.

Hervey, Helen. “The Private Language Problem.” *Philosophical Quarterly* 7 (1957): 63–79. Accepts PLT* but claims that the real problem is whether or not one can recognize and classify one’s sensations apart from their outward expression.

Tanburn, N. P. “Private Languages Again.” *Mind* 72 (1963): 88–102. Attacks PLT-2 and the thesis that all entities referred to in conversation must be publicly available.

Thomson, J. F. “Comments.” In *Knowledge and Experience*, edited by C. D. Rollins. In his part of the symposium with Castañeda and Chappell, Thomson contends that the PLT is too unclear for decision.

Todd, W. “Private Languages.” *Philosophical Quarterly* 12 (1962): 206–217. Argues that “a private language, in the sense of a personal sensation language, is logically possible,” refutes certain arguments of Malcolm, and attempts to show that a private language need not lack criteria of correctness.

Wellman, Carl. “Wittgenstein and the Egocentric Predicament.” *Mind* 68 (1959): 223–233. Discusses critically some of Wittgenstein’s arguments for the PLT in connection with the view that all knowledge is based on private experiences.

Héctor-Neri Castañeda (1967)

PRIVATE LANGUAGE PROBLEM [ADDENDUM]

Although the proper formulation and assessment of Ludwig Wittgenstein’s argument (or arguments) against the possibility of a private language continues to be disputed, the issue has lost none of its urgency. At stake is a broadly

Cartesian conception of experiences that is found today in much philosophy of mind.

WHAT IS A PRIVATE LANGUAGE?

In §243 of *Philosophical Investigations* (1967; see also §256) Wittgenstein introduces the idea of a language in which “a person could write down or give vocal expression to his inner experiences—his feelings, moods, and the rest—for his private use. ... The individual words of this language are to refer to what can only be known to the person speaking; to his immediate private sensations. So another person cannot understand the language.” In subsequent sections (according to some commentators, up to as far as §315) Wittgenstein criticizes the possibility of such a “private language,” and this is where “the private language argument” is usually supposed to be located.

Following the main essay, suppose that Privatus speaks Privatish, a private language. §243 suggests that Privatish has two features:

- (1) Privatish contains a referring expression *n* that refers to one of Privatus’s “immediate private sensations” *s*.
- (2) *s* “can only be known to” Privatus.

According to Wittgenstein Privatish has a third feature, which he apparently thinks follows from (1) and (2):

- (3) *n* can only be understood by Privatus (and, hence, Privatish can only be completely understood by Privatus).

At this point three questions arise. First, what does (2) mean? Second, what sort of referring expression is *n*? Third, why is (3) supposed to follow from (1) and (2)?

By (2) Wittgenstein seems to mean that only Privatus can know whether he is having *s*. “The essential thing about private experience is ... that nobody knows whether other people also have *this* or something else” (§272, see also §246). Of course, this conception of sensations is held by Wittgenstein’s opponent (a defender of the possibility of a private language), not Wittgenstein himself.

As to the referring expression *n*, it is a name, not a description (e.g., “the private sensation caused by pin-pricks”) (see §§256–257). Not even Wittgenstein’s opponent would accept that to understand a description that in fact refers to sensation *s* one has to know that it refers to *s*.

Is *n* a proper name of a token sensation, or is it a common noun referring to a type of sensation? If *n* refers

to a token sensation, something occurring only in the mind of Privatus, then Wittgenstein’s opponent looks exactly like Bertrand Russell in “The Philosophy of Logical Atomism” (1918/1956; see also Candlish 2004). According to Russell, “[i]n order to understand a proposition in which the name of a particular occurs, you must already be acquainted with that particular” (1918/1956, p. 204; see also Russell 1912, chapter 5). Since, on Russell’s view, the only particular things with which one is acquainted are private items he calls *sense-data* (and, in addition, perhaps one’s self), no two people can be acquainted with the same particular, and so no two people can understand a genuine name (as Russell puts it, a name in the “logical sense”). Hence, Russell thinks, if Privatus’s name *n* refers to a token sensation, no one else can understand it.

However, it is clear that Wittgenstein takes the sensations in question to be types, not tokens (see, in particular, §258); accordingly, the name *n* is a common noun. But then Russell’s views about acquaintance and understanding play no role in the justification of (3), for Russell holds that two people can be acquainted with the same property (or type), including properties of private objects. Thus, if Privatus is acquainted with a certain type of sensation *s*, that is no barrier, on Russell’s view, to others also being acquainted with *s*.

So why does Wittgenstein think that (3) follows from (1) and (2)? His argument may be this: one cannot know that Privatus’s name *n* refers to *s*, so one cannot know what *n* means, and hence one cannot understand it. But it is not obvious that knowledge that *n* refers to *s* is necessary for understanding *n*, or for successful communication using it: perhaps all that is required is that one believes that Privatus’s name *n* refers to *s*. The upshot is that Wittgenstein’s double characterization of a private language as one “which describes my inner experiences and which only I myself can understand” (§256) is contentious. (This point is due to Edward Craig [1982]; for further discussion see Craig [1997].)

Given that the two characterizations of a private language should be separated, it is probably better to use the first, leaving the second as a disputed consequence. Thus, a private language may be explained as one containing names for types of inner experiences, with the further stipulation that, if there are any inner experiences, no one knows whether others have the same types of inner experiences as him- or herself.

§258

§258 contains the famous example of keeping “a diary about the recurrence of a certain sensation,” and most commentators identify it as the core of the private language argument. The key move in this section is to cast doubt on whether the diary keeper can “impress on [himself] the connexion between the sign [“S”] and the sensation,” and so “remember the connexion *right* in the future.” Anthony Kenny points out, against some commentators, that “remembering the connexion right” does not mean that one correctly applies “S” to one’s sensation, but that one remembers the meaning of S (1973, pp. 191–193).

Supposedly, there is no fact about the meaning of “S” for the diarist to remember because there is “no criterion of correctness.” Here, there is little consensus on what the missing criterion amounts to, or whether its absence does indeed show that the diarist fails to attach a meaning to “S.” For some representative examples of exegesis, see Malcolm Budd (1989, chapter 3), Stewart Candlish (1980, 2003), John V. Canfield (1991, 2001), Robert J. Fogelin (1987, chapter 12), P. M. S. Hacker (1986, chapter 9; 1990, 61–67); Colin McGinn (1997, chapter 4), David Pears (1988, chapters 13, 14, 15), Scott Soames (2003, chapter 2), and Crispin Wright (1986).

KRIPKE’S WITTGENSTEIN

In *Wittgenstein on Rules and Private Language* (1982), Saul A. Kripke suggests (without unreservedly endorsing) a novel and exciting interpretation of the private language argument (see also Fogelin 1987, p. 241, n. 10). On this interpretation the main argument appears in the earlier long discussion of following a rule starting around §138. As Kripke observes, the conclusion of the private language argument is stated in §202, well before the argument’s traditional location, “Hence it is not possible to obey a rule ‘privately’: otherwise thinking one was obeying a rule would be the same thing as obeying it.” Kripke takes the sections following §243 to be a discussion of a purported counterexample—namely, sensation language—to the conclusion argued for earlier.

The argument Kripke extracts from Wittgenstein is in two parts. The first part purports to establish that there are no facts that make it the case that an individual (Jones, say) means something by a word (addition by “+,” say). This conclusion is reached by canvassing all the plausible candidates for such meaning-constituting facts and finding them all wanting. A *skeptical paradox* (“our paradox” of §201) looms, “no facts, no truth conditions, correspond to such statements such as “Jones means

addition by ‘+’” (1982, p. 77). The second part offers a skeptical solution: “skeptical” because the paradoxical conclusion is embraced; a “solution” because sentences such as “Jones means addition by ‘+’” remain assertible, despite the lack of any “corresponding fact.” And the account of why such sentences are assertible essentially involves a linguistic community, so that if Jones is “considered in isolation,” he cannot be said to mean anything by his words. This is the most general sense in which a “private language” is impossible: An individual considered in isolation from other speakers cannot be said to speak a language (see Kripke 1982, pp. 109–110).

Most commentators have not endorsed Kripke’s interpretation (in particular, see Baker and Hacker 1984, chapter 1; McGinn 1984, chapter 2). However, Kripke’s Wittgenstein has become a philosopher of considerable interest in his own right.

THE COMMUNITY VIEW

Kripke’s book revived interest in the issue of whether the private language argument and related material on rule following is supposed to exclude a Robinson Crusoe isolated from birth from speaking a language (discussion of this topic goes back to Alfred J. Ayer [1954] and Rush Rhees [1954]; see also Kripke [1982, p. 110, n. 84]). While the characterization of a private language in §243 seems to leave room for such a Crusoe, other sections, notably §198, suggest the opposite. Norman Malcolm (1986, 1989) offers a defense of the “community view,” and is countered by G. P. Baker and Hacker (1990). The community view is rejected by most commentators; for further discussion and references, see Canfield (1996).

Alex Byrne (2005)

PROBABILITY AND CHANCE

The weather report says that the chance of a hurricane arriving later today is 90 percent. Forewarned is forearmed: Expecting a hurricane, before leaving home I pack my hurricane lantern.

Probability enters into this scenario twice, first in the form of a physical probability, sometimes called a chance, quantifying certain aspects of the local weather that make a hurricane very likely, and second in the form of an epistemic probability capturing a certain attitude to the proposition that a hurricane will strike, in this case one of considerable confidence.

It is not immediately obvious that these two probabilities are two different kinds of thing, but a *prima facie* case can be made for their distinctness by observing that they can vary independently of one another: For example, if the meteorologists are mistaken, the chance of a hurricane may be very low though both they and I am confident that one is on its way.

Most philosophers now believe that the apparent distinctness is real. They are therefore also inclined to say that my belief that the physical probability of a hurricane is very high is distinct from my high epistemic probability for a hurricane. There must be some principle of inference that takes me from one to the other, a principle that dictates the epistemic impact of the physical probabilities—or at least, of my beliefs about the physical probabilities—telling me, in the usual cases, to expect what is physically probable and not what is physically improbable. One can call such a principle, mediating as it does between two different kinds of probability, a probability coordination principle.

The three principal topics of this entry will be, in the order considered, epistemic probability, physical probability, and probability coordination. Two preliminary sections will discuss the common mathematical basis of epistemic and physical probability and the classical notion of probability.

THE MATHEMATICAL BASIS

What all probabilities, epistemic and physical, have in common is a certain mathematical structure. The most important elements of this structure are contained in the axioms of probability, which may be paraphrased as follows:

- (1) All probabilities are real numbers between zero and one inclusive (for any proposition a , $0 \leq P(a) \leq 1$).
- (2) The probability of an inconsistent proposition is zero; the probability of a logical truth, or tautology, is one.
- (3) The probability that either one or the other of two mutually exclusive propositions is true is equal to the sum of the probabilities of the individual propositions. (Two propositions are mutually exclusive if they cannot both be true; the *cannot* is interpreted as a matter of logical consistency, so that the axiom says that for any two propositions a and b such that $a \vdash \neg b$, $P(a \vee b) = P(a) + P(b)$.)

The axioms as stated here assume that probabilities are attached to propositions, such as the proposition that “A hurricane will strike New York at some time on the afternoon of January 20, 2005.” The axioms may also be stated in a way that assumes that probabilities attach to events. It is more natural to attach epistemic probabilities to propositions and physical probabilities to events, but when the two kinds of probability are discussed side by side it is less confusing, and quite tolerable, to take propositions as the primary bearers of both kinds of probability. Nothing important is thought to turn on the choice.

The three axioms of probability, though simple, may be used to prove a wide range of interesting and strong mathematical theorems. Because all probabilities conform to the axioms, all probabilities conform to the theorems. It is possible, then, to do significant work on probability without presupposing either epistemic or physical probability as the subject matter, let alone some particular construal of either variety. Such work is for the most part the province of mathematicians.

Philosophical work on probability may also be mathematical, but is most often directed to one or the other variety of probability, usually attempting a philosophical analysis of probability statements made in a certain vein, for example, of probability claims made in quantum mechanics or evolutionary biology (both apparently claims about physical probability) or of probability claims made in statistical testing or decision theory (both apparently claims about epistemic probability).

Two important notions encountered in statements of the mathematical behavior of probability are conditional probability and probabilistic independence. Both are introduced into the mathematics of probability by way of definitions, not additional axioms, so neither adds anything to the content of the mathematics.

CONDITIONAL PROBABILITY. The probability of a proposition a conditional on another proposition b , written $P(a|b)$, is defined to be $P(ab)/P(b)$, where ab is the conjunction of a and b . (The conditional probability is undefined when the probability of b is zero.) For example, the probability of obtaining three heads on three successive tosses of a coin, conditional on the first toss yielding heads, is the probability of obtaining three heads in a row, namely one-eighth, divided by the probability of obtaining heads on the first coin, namely one-half—in other words, one-quarter.

Some writers suggest taking conditional probability as the basis for all of probability mathematics, a move that allows, among other things, the possibility of conditional probabilities that are well defined even when the probabilities of the propositions conditionalized on are zero (Hájek 2003). On this view, the mathematical posit stated above linking conditional and unconditional probabilities is reinterpreted as an additional axiom.

The act of conditionalization may be used to create an entirely new probability distribution. Given an old probability distribution $P(\dot{s})$ and a proposition b , the function $P(\dot{s}|b)$ is provably also, mathematically speaking, a probability distribution. If k is a proposition stating all of one’s background knowledge, for example, then a new probability distribution $P(\dot{s}|k)$ can be formed by conditionalizing on this background knowledge, a distribution that gives, intuitively, the probabilities for everything once one’s background knowledge is taken into account. This fact is especially important in the context of epistemic probability.

PROBABILISTIC INDEPENDENCE. Two propositions a and b are probabilistically independent just in case $P(ab) = P(a)P(b)$. When the probability of b is nonzero, this is equivalent to $P(a|b) = P(a)$, or in intuitive terms, the claim that the truth or otherwise of b has no impact on the probability of a .

Several of the most important and powerful theorems in probability mathematics make independence assumptions. The theorem of most use to philosophers is the law of large numbers. The theorem says, very roughly, when a large, finite set of propositions are independent, but have the same probability p , then the proportion of propositions that turn out to be true will, with high probability, be approximately equal to p . (The generalization to countably infinite sets of propositions is easy if the propositions are ordered; substitute *limiting frequency* for *proportion*.)

For example, the propositions might all be of the form “Coin toss x will produce heads,” where the x stands for any one of a number of different tosses of the same coin. If the probability of each of the propositions is one-half, then the law of large numbers says, in effect, that provided the tosses are independent, it is very likely that about one-half will yield heads.

It is natural to interpret the probabilities in this example as physical probabilities, but the law of large numbers applies equally to any kind of probability, provided that independence holds. There are, in fact, many variants of the law of large numbers, but the details are beyond the scope of this entry.

CLASSICAL PROBABILITY

The development of the mathematics, and then the philosophy, of probability was spurred to a perhaps surprising degree by an interest, both practical and theoretical, in the properties of simple gambling devices such as rolled dice, tossed coins, and shuffled cards. Though there was from the beginning a great enthusiasm for extending the dominion of the “empire of chance” to the ends of the earth, gambling devices were—and to some extent are still—the paradigmatic chance setups.

A striking feature of gambling devices is their probabilistic transparency: The discerning eye can “read off” their outcomes’ physical probabilities from various physical symmetries of the device itself, seeing in the bilateral symmetry of the tossed coin a probability of one-half each for heads and tails, or in the six-way symmetry of the die a probability of one-sixth that any particular face is uppermost at the end of a roll (Strevens 1998).

The classical definition of probability, paramount from the time of Gottfried Wilhelm Leibniz to the time of Pierre Simon de Laplace (the late seventeenth century to the early nineteenth century) takes its inspiration from the alignment of probability with symmetry. The best-known formulation of the classical account is due to Laplace:

The theory of chance consists in reducing all the events of the same kind to a certain number of cases equally possible, that is to say, to such as we may be equally undecided about in regard to their existence, and in determining the number of cases favorable to the event whose probability is sought. The ratio of this number to that of all the cases possible is the measure of this probability, which is thus simply a fraction whose numerator is the number of favorable cases and

whose denominator is the number of all the cases possible. (1902, pp. 6–7)

As many commentators note, this formulation, typical of the classical probabilists, appears to involve two parallel definitions, the first based on the notion of equal possibility and the second on the notion of equal undecidedness. Laplace’s relation of equal possibility between two cases probably ought to be understood as picking out a certain physical symmetry in virtue of which the cases have equal physical probabilities. All classical probabilities, on the equal possibility definition, have their basis in such physical symmetries, and so would seem to be physical probabilities. The relation of equal undecidedness between two cases refers to some sort of epistemic symmetry, though perhaps one founded in the physical facts. A probability with its basis in undecidedness would seem to be, by its very nature, an epistemic probability. Classical probability, then, is at the same time a kind of physical probability and a kind of epistemic probability.

This dual nature, historians argue, is intentional (Hacking 1975, Daston 1988). In its epistemic guise classical probability can be called on to do work not normally thought to lie within the province of an objective notion of probability, such as measuring the reliability of testimony, the strength of evidence for a scientific hypothesis, or participating in decision-theoretic arguments such as Blaise Pascal’s famous wager on the existence of God. In its physical guise classical probability is able to cloak itself in the aura of unrevisability and reality that attaches to the gambling probabilities such as the one-half probability of heads.

The classical definition could not last. Gradually, it came to be acknowledged that although the epistemic probabilities may, or at least ought to, shadow the physical probabilities wherever the latter are found, they play a number of roles in which there is no physical probability, nor anything with the same objective status as a physical probability to mimic. The classical definition was split into its two natural parts, and distinct notions of physical and epistemic probability were allowed to find their separate ways in the world.

At first, in the middle and late nineteenth century, physical probability commanded attention almost to the exclusion of its epistemic counterpart. Developments in social science, due to Adolphe Quetelet (1796–1874), in statistical physics, due to James Clerk Maxwell and Ludwig Boltzmann, and eventually (around 1930) in the synthesis of evolutionary biology and genetics, due to Ronald Aylmer Fisher and many others, turned on the successful deployment of physical probability distributions. Begin-

ning in the early twentieth century, however, epistemic probability came into its own, freeing itself over the decades from what came to be seen as the classical probabilists' futile attempt to provide strict guidelines dictating unique rational epistemic probabilities in every situation.

Modern philosophy remade itself in the twentieth century, imposing a historical horizon at around 1900. The story of the interpretation of probability is often told beginning near that year, with the result that the development of epistemic probability, and logical probability in particular, comes first—a convention that will be followed here.

EPISTEMIC PROBABILITY

Epistemic probability takes two forms. In its first form, it is a measure of a person's degree of confidence in a proposition, increasing from zero to one as his or her attitude goes from almost total disbelief to near certainty. This kind of epistemic probability is called credence, degree of belief, or subjective probability. The propositional attitude one gets when one attaches a subjective probability to a proposition is sometimes called a partial belief.

In its second form, associated most often with the term *logical probability*, epistemic probability measures the impact of a piece or pieces of evidence on a proposition. Its elemental form may not be that of a probability distribution, in the usual sense, but it is related to a probability distribution in some straightforward way, and as will be seen shortly, is quite capable of providing a basis for a complete system of epistemic probability.

There is a foundational dispute between the proponents of the two forms of epistemic probability. It is not a fight for existence but for primacy: The question is which of the two kinds of epistemic probability is the more epistemologically basic.

LOGICAL PROBABILITY. The second form of epistemic probability has, since 1900, most often taken the guise of logical probability. A logical probability is attached not to a proposition but to a complete inductive inference. It is a measure of the degree to which the evidence contained in the premises of an inductive inference, considered in isolation, probabilifies the conclusion. The idea of probabilistic inference was an important part of classical probability theory, but from the post-1900 perspective it is associated first with John Maynard Keynes (1921)—who was more famous, of course, as an economist.

In explaining the nature of logical probability, and in particular the tag *logical* itself, Keynes draws a close analogy with deductive inference: Whereas in a deductive inference the premises entail the conclusion, in an inductive inference they partially entail the conclusion, the degree of entailment being represented by a number between zero and one, namely, a logical probability. (Note that a degree zero entailment of a proposition is equivalent to full entailment of the proposition's negation.) Just as the first form of epistemic probability generalizes from belief to partial belief, then, the second form generalizes, in Keynes's hands, from entailment to partial entailment.

For example: Take as a conclusion the proposition that the next observed raven will be black. A proposition stating that a single raven has been observed to be black might entail this conclusion only to a relatively small degree, this logical probability representing the slightness of a single raven's color as evidence for the color of any other raven. A proposition stating that many hundreds of ravens have been observed to be black will entail the conclusion to some much greater degree.

It is an objective matter of fact whether one proposition deductively entails another; so, Keynes conjectured, it is in many cases a matter of objective fact to what degree one proposition partially entails another. These facts themselves comprise inductive logic; the logical probabilities are at base, then, logical entities, just as the name suggests.

Although exact logical probabilities are for Keynes the ideal, he allows that in many cases logic will fix only an approximate degree of entailment for an inductive inference. The presentation in this entry will for simplicity's sake focus on the ideal case.

Keynes's logical probability is not only compatible with subjective probability, the other form of epistemic probability; it also mandates certain values for a person's subjective probabilities. If the premises in an inductive inference are known for certain, and they exhaust the available evidence, then their inductive impact on the conclusion—the degree of entailment, or logical probability attached to the inference, from the premises to the conclusion—is itself the degree of belief, that is, the subjective probability, that a rational person ought to attach to the conclusion, reflecting as it does all and only the evidence for the conclusion.

Keynes uses this argument as a basis for taking as a formal representation of logical probabilities the probability calculus itself: The degree to which proposition *b* entails proposition *a* is written as a conditional probabil-

ity $P(a|b)$. Note that these probabilities do not change as the evidence comes in, any more than facts about deductive entailment can change as the evidence comes in. The logical probability $P(a|b)$ must be interpreted as a quantification of the inductive bearing of b alone on a , not of b together with some body of accepted knowledge.

The unconditional probability $P(a)$, then, is the inductive bearing on a of an empty set of evidence—the degree to which a is entailed, in Keynes's sense, by the set of logical truths, or tautologies, alone. One might think that the degree of entailment is zero. But this cannot be right: If one has no evidence at all, one must set one's subjective probabilities for both a and its negation equal to their respective degrees of entailment by the tautologies. But one cannot set both subjective probabilities to zero—it cannot be that one is certain that neither a nor its negation is true, since one of the two must be true. One's complete lack of evidence would be better represented by setting both subjective probabilities to intermediate values, say one-half. The logical probabilist, in endorsing this assignment, implicitly asserts that the empty set of evidence, or the set of tautologies, entails both a and its negation to degree one-half.

Although its subject matter is the bearing of evidence on hypotheses, then, logical probability theory finds itself having to take a position on what one should believe when one has no evidence (under the guise of the question of the tautologies' partial entailments). To answer this question, it has turned to the principle of indifference, which recommends—when there is no evidence favoring one of several mutually exclusive possibilities over the others—that the available probability be equally distributed among them. This is, of course, the same principle that comprises one strand of the classical definition of probability: Laplace suggested assigning equal probabilities to cases “such as we may be equally undecided about in regard to their existence” (Laplace 1902, p. 6). It has also played an important role in the development of the theory of subjective probability, and so is discussed in a separate section later in this entry.

As the role of indifference shows, logical probability is close in spirit to the epistemic strand of classical probability. It posits, at least as an ideal, a single system of right reasoning, allowing no inductive latitude whatsoever, to which all rational beings ought to conform. Insofar as rational beings ever disagree on questions of evidential impact, it must be because they differ on the nature of the evidence itself.

Many philosophers find this ideal of inductive logic hard to swallow; even those sympathetic to the idea of

strong objective constraints on inductive reasoning are often skeptical that the constraints take the form of logical truths, or something analogous to logical truths. This skepticism has two sources.

First is the perception that inductive practices vary widely. Whereas there exists a widespread consensus as to which propositions deductively entail which other propositions, there is no such consensus on degrees of evidential support. That is not to say, of course, that there is disagreement about every aspect of inductive reasoning, but there is far less agreement than would be necessary to build, in the same way that deductive logic was constructed, a useful inductive logic.

Second, there are compelling (though not irresistible) reasons to believe that it is impossible to formulate a principle of indifference that is both consistent and strong enough to do the work asked of it by logical probabilists. These reasons are sketched in the discussion of the principle later on.

Rudolf Carnap (1950) attempted to revive the idea of a system of induction founded on logic alone in the mid-century. His innovation—drawing on his general philosophy of logic—was to allow that there are many systems of inductive logic that are, from a purely logical viewpoint, on a par. One may freely choose from these a logic, that is, a set of logical probabilities, that suits one's particular nonlogical ends.

Carnap relativized induction in two ways. First, his version of the principle of indifference was indexed to a choice of language; how one distributes probability among rival possibilities concerning which one knows nothing depends on one's canonical system for representing the possibilities. Second, even when a canonical language is chosen, Carnap's rule for determining inductive support—that this, degrees of entailment or logical probabilities—contains a parameter whose value may be chosen freely. The parameter determines, roughly, how quickly one learns from the evidence. Choose one extreme, and from the observation of a single black raven one will infer with certainty that the next raven will also be black (straight induction). Choose the other extreme, and no number of black ravens is great enough to count as any evidence at all for the blackness of the next raven. A sensible choice would seem to lie somewhere in the middle, but on Carnap's view, logic alone determined no preference ranking whatsoever among the different choices, rating all values apart from the extremes as equally good.

Carnap did give extralogical arguments for preferring a particular value for the parameter, arriving at an inductive rule equivalent to Laplace's rule of succession. Given that, say, i out of n observed ravens have been black, both Carnap and Laplace assign a probability of $(i + 1)/(n + 2)$ to the proposition that the next raven will be black.

One awkward feature of Carnap's system is that, no matter what value is chosen for the inductive parameter, universal generalizations cannot be learned: The inductive bearing of any number of black ravens on the hypothesis "All ravens are black" is zero.

Carnap's system is of great intrinsic interest, but from the time of its presentation, its principal constituency—philosophers of science—was beginning to move in an entirely different direction. Such considerations as Nelson Goodman's new riddle of induction and arguments by Bayesians and others that background knowledge played a part in determining degrees of inductive support, though not beyond the reach of Carnap's approach, strongly suggested that the nature of inductive support could not be purely logical.

Today, the logical approach to inductive inference has been supplanted to a great extent by (though not only by) the Bayesian approach. Still, in Bayesianism itself some have seen the seeds of a new inductive logic.

SUBJECTIVE PROBABILITY. Whereas logical probability is a logical entity—a quantification of the supposed logical facts about partial entailment—the other kind of epistemic probability, subjective probability, is a psychological entity, reflecting an actual cognitive fact about a particular person or (if they are sufficiently agreed) a group of people. The rationality of a person's subjective probabilities may be a matter of logic, then, but the probabilities themselves are a matter of psychology.

That for a number of propositions one tends to have a degree of confidence intermediate between the extremes associated with total disbelief and total belief, no one will deny. The advocates of subjective probability as a key epistemological notion—who call themselves Bayesians or simply subjectivists—go much further than this. They characteristically hold that humans have, or ought to have, well-defined subjective probabilities for every proposition and that these subjective probabilities play a central role in epistemology, both in inductive inference, by way of Thomas Bayes's (1702–1761) conditionalization rule, and in practical deliberation, by way of the usual mechanisms of decision theory.

The subjectivist's first challenge is to give a substantial characterization of subjective probability and to argue that subjective probabilities are instrumental in human cognition, while at the same time finding a foothold in the descriptive, psychological scheme for the normative concerns of epistemology. Much of this groundwork was laid in Frank Plumpton Ramsey's influential paper "Truth and Probability" (1931).

Ramsey does not define subjective probability as such, and even goes so far as to acknowledge that the ideal of a definite subjective probability for every proposition is just that—an ideal that goes a long way toward capturing actual human epistemology without being accurate in every respect. What he posits instead is a connection—whether conceptual or empirical he does not say—between the value of a person's subjective probability for a proposition and his or her betting behavior.

If one has a subjective probability p for a proposition a , Ramsey claims, one will be prepared to accept odds of up to p : $(1 - p)$ on the truth of a . That is, given a game in which one stands to win $\$n$ if a is true, one will pay up to $\$pn$ to play the game; equivalently, if one will pay up to $\$m$ to play a game in which one stands to win $\$n$ if a is true, one's subjective probability for a must be m/n . (Decision theorists, note, talk about utility, not dollars.)

Importantly, all human choice under uncertainty is interpreted as a kind of betting. For example, suppose I have to decide whether to wear a seat belt on a long drive. I am in effect betting on whether I will be involved in an auto accident along the way. If the cost of wearing a belt, in discomfort, inconvenience, and forsaken cool, is equivalent to losing $\$m$, and the cost of being beltless in an accident, in pain, suffering, and higher insurance premiums, is $\$n$, then I will accept the risk of going beltless just in case my subjective probability for there being an accident is less than or equal to m/n . (Here, the "prize" is negative. The cost of playing is also negative, so just by agreeing to play the game, I gain something: the increase in comfort, cool, and so on. My aim is to play while avoiding a win.) The central doctrine of decision theory is, then, built into the characterization of subjective probability.

Ramsey (1931) uses this fact to argue that, provided a person's behavior is coherent enough to be described, at least approximately, by the machinery of decision theory, his or her subjective probabilities for any proposition may be inferred from his or her choices. In effect, the person's subjective probabilities are inferred from the nature of the bets, in the broadest sense, he or she is prepared to accept. Because one's overt behavior can be systematized,

approximately, using a decision-theoretic framework, one must have subjective probabilities for every proposition, and these probabilities must play a central role in one's decision theory.

What is the force of the *must* in the preceding sentence? That depends on the nature of the posit that one having a certain subjective probability for a proposition means that one is prepared to accept certain odds on the proposition's being true. Some writers, especially in the midcentury heyday of conceptual analysis and psychological behaviorism, interpret the posit as a definition of subjective probability; on this view, one having certain subjective probabilities just is one having a certain betting behavior. Others, like Ramsey (1931), opt for a looser connection. On any approach, there is a certain amount of latitude in the phrase "prepared to accept." If I am prepared to accept certain odds, *must* I play a game in which I am offered those odds? Or only if I am in a betting mood? The former answer vastly simplifies the subjectivist enterprise, but at a cost in psychological plausibility: It is surely true that people frequently gamble in the broad sense that they take measured risks, but it is not nearly so obvious that they are compulsive gamblers intent on taking on every favorable risk they can find. Work on the psychology of decision making also suggests that it is a mistake to found the subjectivist enterprise on too strong a conception of the connection between subjective probability and betting behavior.

Subjective probabilities are supposed to conform, as the name suggests, to the axioms of probability theory. In a theory such as Ramsey's (1931), a certain amount of probability mathematics is built into the technique for extracting the subjective probabilities; that humans not only have subjective probabilities, but arrange them in accord with the axioms, is a condition for the success of Ramsey's (1931) project.

Insofar as subjective probability is not simply defined as whatever comes out of the Ramsey project, however, there is a question whether subjective probabilities obey the axioms. If they do not, there is little that they are good for, so the question is an important one for subjectivists, who tend to follow Ramsey in giving a normative rather than a descriptive answer: It is rational to arrange one's subjective probabilities in accordance with the axioms. (It is not unreasonable, of course, to see this normative claim, if true, as evidence for the corresponding descriptive claim, since humans are in certain respects reliably rational.)

The vehicle of Ramsey's argument is what is called the Dutch book theorem: It can be shown that, if one's

subjective probabilities violate the axioms, then one will be prepared to accept certain sets of bets (which bets depends on the nature of the violation) that will cause one a sure loss, in the sense that one will lose whether the propositions that are the subjects of the bets turn out to be true or false.

The details of the argument are beyond the scope of this entry (for a more advanced introduction, see Howson and Urbach 1993), but an example will illustrate the strategy. The axioms of the probability calculus require that the probability of a proposition and that of its negation sum to one. Suppose one violates this axiom by assigning a probability of 0.8 both to a certain proposition a and to its negation. Then one is prepared to accept odds of 4:1 on both a and $\neg a$, which means a commitment to playing, at the same time, two games, in one of which one pays \$8 and wins \$10 (i.e., one's original \$8 plus a \$2 profit) if a is true, and in one of which one pays \$8 and wins \$10 if a is false. Whether a is true or false, one pays \$16 but wins only \$10—a certain loss. To play such a game is irrational; thus, one should conform one's subjective probabilities to the probability calculus. Needless to say, the Dutch book argument works best on the dubious interpretation of "prepared to accept" as equivalent to "compelled to accept"; there have been many attempts to reform or replace the argument with something that makes weaker, or even no, assumptions about betting behavior.

Subjectivism has been developed in several important directions. First are various weakenings or generalizations of the subjectivist machinery. The question of the connection between subjective probability and betting behavior is, as noted, one locus of activity. Another attempts to generalize the notion of a subjective probability to a subjective probability interval, the idea being that where one does not have an exact subjective probability for a proposition, one may have an approximate level of confidence that can be captured by a mathematical interval, the equivalent of saying that one's subjective probability is indeterminately somewhere between two determinate values.

Second, and closely related, is all the work that has been put into developing decision theory over the last 100 years (e.g., see Jeffrey 1983). Finally, subjectivism provides the foundation for the Bayesian theory of inference. At the root of the Bayesian system is a thought much like the logical probabilist's doctrine that, if k is one's background knowledge, then one's subjective probability for a hypothesis a ought to be $P(a|k)$. Whereas for a logical probabilist a conditional probability $P(a|b)$ is a timeless

logical constant, for a subjectivist it is something that constantly changes as further evidence comes in (even holding a and b fixed). For this reason, the subjectivist theory of inference must be an inherently dynamic theory; what is perhaps its best-known weakness, the “problem of old evidence,” arises from this fact.

Subjectivism had almost entirely eclipsed logical probabilism by the late twentieth century; as the celestial metaphor unwittingly implies, however, there is a cyclic aspect to philosophical history: An interest in the central notion of logical probability theory, evidential weight, is on the rise.

There are three strands to this new movement. First is the perception among philosophers of science that scientific discourse about evidence is almost never about the subjective probability scientists should have for a hypothesis, and almost always about the degree of support that the evidence lends to the hypothesis. Second is the development of new and safer (though limited) versions of the principle of indifference. Third is technical progress on the project of extracting from the principles of Bayesian inductive inference a measure of weight. Note that this third project conceives of inductive weight as something derived from the more basic Bayesian principles governing the dynamics of subjective probability, a view opposed to the logical probabilists’ derivation of rational subjective probabilities from the (by their lights) more basic logical principles governing the nature of inductive support.

INDIFFERENCE. The principle of indifference distributes probability among various alternatives—in the usual case, mutually exclusive and exhaustive propositions—concerning which little or nothing is known. The principle’s rationale is that certain probability distributions reflect ignorance better than others. If I know nothing that distinguishes two mutually exclusive possibilities, picked out by propositions a and b , then I have no reason to expect one more than the other: I should assign the propositions equal probabilities. Any asymmetric assignment, say assigning twice the probability to a that I assign to b , would reflect some access on my part to facts supporting a at the expense of b . Thus, ignorance and probabilistic symmetry ought to go hand in hand—or so the principle of indifference would have it.

The principle is an essential part of logical probability theory, for the reasons given earlier, but there have always been subjectivists who appeal to the principle as well. It is most useful within the Bayesian approach to inductive inference.

The epistemic strand of classical probability theory also invokes the principle, of course, blending it with the discernment of “equally possible cases” in the paradigmatic gambling setups. This conflation has confused the discussion of the principle ever since, with proponents of the principle continuing to take aid and comfort in the principle’s apparent virtuoso handling of cases such as the one-half probability of heads. One’s reasoning about the gambling probabilities, however, as the classical probabilists for the most part themselves dimly saw, is a matter of inferring physical probabilities from physical symmetries, not of setting epistemic probabilities to reflect symmetric degrees of ignorance (Strevens 1998).

The most famous arguments against the principle of indifference were developed in the nineteenth century, which was a time of hegemony for physical over epistemic probability. They take their name from Joseph Bertrand (1822–1900), who pointed to the difficulty of finding a unique symmetry in certain indifference-style problems.

Consider, for example, two leading theories of dark matter in the universe: the MACHO and the WIMP theories. Each posits a certain generic form for dark matter objects, respectively large and small. If one has no evidence to distinguish them, it seems that the principle of indifference directs one to assign each a probability of one-half (assuming for the sake of the argument that there are no other possibilities). But suppose that there are four distinct schools of thought among the MACHO theorists, corresponding to four distinct ways that MACHOs might be physically realized, and eight such schools of thought among WIMP theorists. Now there are twelve possibilities, and once probability is distributed equally among them, the generic MACHO theory will have a probability of one-third and the WIMP theory a probability of two-thirds. Cases such as this make the principle seem capricious, if not simply inconsistent (as it would be if it failed to pick out a privileged symmetry).

Matters become far worse, as Bertrand noted, when there are uncountably many alternatives to choose among, as is the case in science when the value of a physical parameter, such as the cosmological constant, is unknown. Even in the simplest of such cases, the principle equivocates (Van Fraassen 1989, chapter 12). As noted earlier, some progress has been made in solving these problems, with Edwin T. Jaynes (1983) being a ringleader. Most philosophers, though, doubt that there will ever be a workable principle of indifference suited to the needs of general inductive inference.

PHYSICAL PROBABILITY

The paradigms of physical probability are the probabilities attached to gambling setups; there are, however, many more interesting examples: the probabilities of quantum mechanics and kinetic theory in physics, the probabilities of population genetics in evolutionary theory, actuarial probabilities such as the chance of dying before reaching a certain age, and the probabilities in many social science models. It is by no means clear that there is a single phenomenon to be explained here; the physical probabilities ascribed to phenomena by the best scientific theories may differ in their makeup from theory to theory. There is a commonality in the phenomena themselves, however: Whenever the notion of physical probability is put to scientific work, it is to predict or explain what might be called probabilistic patterns of outcomes. These patterns are characterized by a certain kind of long-run order, discernible only over a number of different outcomes, and a certain kind of short-term disorder, the details of the order and disorder depending on the variety of probability distribution.

The simplest and best-known of the patterns is the Bernoulli pattern, which takes its name from the corresponding probability distribution. This is the pattern typical of the outcomes produced by gambling devices, such as the pattern of heads and tails obtained by tossing a coin. The long-term order takes the form of a stable frequency equal to the corresponding probability. In the case of the tossed coin, this is of course the one-half frequency with which heads and tails occur (almost always) in the long run. The short-term disorder, though an objective property of the pattern itself, is perhaps best gotten at epistemically: Once one knows that the long-run frequency of heads is one-half, the outcome of one toss provides no useful information about the outcome of the next. The law of large numbers implies that a chance setup will produce its characteristic probabilistic patterns in the long run with very a high (physical) probability. When discussing physical probability, it is more natural to talk of probabilities attaching to events than to propositions; what follows will be formulated accordingly.

THE FREQUENCY THEORY The frequentist theory of physical probability has its roots in the empiricist interpretation of law statements according to which they assert only the existence of certain regularities in nature (on the regularity theory, see Armstrong 1983). What is usually called the actual frequency theory of probability understands physical probability statements, such as the claim that the probability of a coin toss's yielding heads is

one-half, as asserting in a like spirit the existence of the appropriate probabilistic patterns—in the case of the coin toss, for example, a pattern of heads and tails in the actual outcomes of coin tosses exemplifying both the order and the disorder characteristic of the Bernoulli patterns.

The characteristic order in a Bernoulli pattern is a long-run frequency approximately equal to the relevant probability; in the case of the coin, then, it is a long-run frequency for heads of one-half. It is from this aspect of the pattern that frequentism takes its name. (One complication: A distinction must be made between the case in which the set of events exemplifying the pattern is finite and the case in which it is countably infinite. In a finite case, what matters is the proportion or relative frequency, whereas in the infinite case, it is instead the limiting frequency, that is, the value of the relative frequency in the limit, if it exists, as it must for the Bernoulli pattern to exist.)

Although their account is named for frequencies, most frequentists insist also on the presence of appropriate short-term disorder in the patterns. It is less easy to characterize this disorder in the purely extensional terms implicit in a commitment to regularity metaphysics. Suffice it to say that there is a broad range of characterizations, some strict, some rather lax. Among frequentists, Richard von Mises (1957) tends to a strict and Hans Reichenbach (1949) to a lax requirement (though Reichenbach holds, characteristically, that there is no uniquely correct level of strictness; for a discussion of the technical problems in constructing such a requirement, see Fine [1973]).

The probability that a particular coin toss lands heads is one-half, according to frequentism, because the outcome of the toss belongs to a series that exemplifies the Bernoulli pattern with a frequency of one-half. The truth-maker for the probability claim is a fact, then, about a class of outcomes, not just about the particular outcome to which the probability is nominally attached. But which class? If one is tossing an American quarter, does the class include all American quarters? All American and Canadian quarters? All fair coins? Or—ominously—all coin tosses producing heads? To give an answer to this question is to solve what has become known as the problem of the reference class.

The standard frequentist solution to the problem is to understand probability claims as including a (perhaps implicit) specification of the class. All physical probability claims are, in other words, made relative to a reference class. This doctrine reveals that the frequency theory is

best seen as an account, in the first instance, of statements of statistical laws. A claim about the one-half probability of heads, for example, is on the frequency interpretation in essence a statement of a probabilistic law concerning a class of coin tosses, not a claim about a property of a particular toss.

The kinship between the regularity account of deterministic laws and the frequency account of probability is, then, even closer than it first appears. Note that the regularity account has its own analog of singular probability claims, namely, singular claims about deterministic tendencies, such as a particular brick's tendency to fall to earth when released. Regularity theorists interpret a tendency claim not as picking out an intrinsic property of the object possessing the tendency, but as a veiled law statement.

The case of probability introduces a complication, however, that is not present in the case of exceptionless regularities: A particular coin toss will belong to many reference classes, some with different frequencies for heads. There may be, then, no determinate fact of the matter about an individual coin toss's probabilistic tendency to produce heads, or equivalently, about what are often called single case probabilities. Frequentists have made their peace with this consequence of their view.

Opponents of the frequency view argue that single-case probabilities are metaphysically, inductively, and explanatorily indispensable. Are they right? Here is the case for metaphysical indispensability: Some writers, especially propensity theorists, hold that there is clearly a fact of the matter about the value of the probability that some particular coin toss lands heads, independent of any choice of reference class. Frequentists may simply deny the intuition or may try explain away the appearance of a single-case fact (for related versions of the explanation, see Reichenbach 1949, §68; Strevens 2003, pp. 61–62).

And here is the case for predictive indispensability: To settle, for predictive and decision-theoretic purposes, on a rational subjective probability for an event using the probability coordination principle, a corresponding physical probability must be found (see the discussion of probability coordination later on). The corresponding probability is often understood to be the physical probability of that very event, hence, a single-case probability. Frequentists must find an alternative understanding. Reichenbach proposes using the frequentist probability relative to the narrowest reference class “for which reliable statistics can be compiled” (1949, p. 374).

The case for explanatory indispensability rests principally on the intuition that the probabilistic explanation of a single outcome requires a single-case probability. The philosophy of scientific explanation, much of it developed by regularity theorists and other metaphysical empiricists, offers a number of alternative ways of thinking about explanation, for example, as a matter of showing that the outcome to be explained was to be expected, or as a matter of subsuming the outcome to be explained under a general pattern of outcomes (both ideas proposed by Carl Gustav Hempel). The fate of frequentism, and more generally of the regularity approach to laws of nature, depends to some extent, then, on the adequacy of these conceptions of explanation.

Why be a frequentist? The view has two principal advantages. First is its light metaphysical touch, shared with the regularity account of laws. Second is the basis it gives for the mathematics of probability: Frequencies, as mathematical objects, conform to almost all the axioms of probability. Only almost all because they violate the axiom of countable additivity, an extension to the countably infinite case of the third axiom described earlier. Countable additivity plays an important role in the derivation of some of probability mathematics' more striking results, but whether it is necessary to provide a foundation for the scientific role of physical probability claims is unclear.

There is more than one way to be a frequentist. A naive actual frequentist holds that there is a probability wherever there is a frequency, so that, in a universe where only three coin tosses have ever occurred, two coming up heads, there is a probability for heads of two-thirds. This view has been widely criticized, though never held. Compare with the naive regularity theory of laws (Armstrong 1983, §2.1).

What might be called ideal actual frequentism is the theory developed by Reichenbach (1949) and von Mises (1957). On this view, probability statements are construed as ideally concerning only infinite classes of events. In practice, however, they may be applied to large finite classes that in some sense come close to having the properties of infinite classes. Thus, Reichenbach distinguishes the logical meaning of a probability statement, which asserts the probabilistic patterning of an infinite class of outcomes, and the finitist meaning that is given to probability claims in physical applications, that is, in the scientific attribution of a physical probability (Reichenbach 1949). On the finitist interpretation, then, a physical probability claim concerns the probabilistic patterning of some actual, finite class of events—albeit a class large

enough to have what Reichenbach calls a practical limiting frequency. (Reichenbach's wariness about logical meaning owes as much, incidentally, to his desire to have his theory of probability conform to the verifiability theory of meaning as to a concern with, say, the validity of probability claims in a finite universe.)

David Lewis (1994), reviving Ramsey's account of laws of nature, proposes that the fundamental laws are nothing but the axioms of the theory that best systematizes, or unifies, the phenomena. A systematization is good to the degree that it is simple, that it makes claims about a large proportion of the phenomena (ideally all the phenomena, of course), and that its claims are accurate. Lewis (1994) extends the definition of accuracy, or as he calls it, fit, to accommodate axioms attributing physical probabilities: A set of phenomena are a good fit to a physical probability statement if the phenomena exemplify the probabilistic patterns appropriate to the probability ascribed. A system of probabilistic axioms will be a good systematization, then, only if the physical probabilities it assigns to the phenomena are reflected, for the most part, in corresponding probabilistic patterns.

In this respect, Lewis's view is a form of frequentism. Although there is not some particular set of outcomes whose probabilistic patterning is necessary and sufficient for the truth of a given probabilistic law statement, it is nevertheless the world's probabilistic patterns, taken as a whole, that provide the basis for all true statements of probabilistic law.

Some writers suggest that a claim such as "The probability of obtaining heads on a toss of this coin is one-half" is equivalent to the claim that, if the coin were tossed infinitely many times, it would yield heads with a limiting frequency of one-half. The truth-makers for physical probability claims, then, are modal facts (except in the case where there actually are an infinite number of tosses). This view is known as hypothetical frequentism.

Though much discussed in the literature, hypothetical frequentism is seldom advocated. Reichenbach (1949) and von Mises (1957) are sometimes labeled hypothetical frequentists, but the textual evidence is thin, perhaps even nonexistent. Colin Howson and Peter Urbach (1993) advocate a hypothetical frequency view. Bas C. van Fraassen's (1980) frequencies are also hypothetical, but because he holds that the literal meaning of theoretical claims is irrelevant to the scientific enterprise, the spirit of his account of probability is, in its empiricism, closer to Reichenbach's ideal actual frequentism.

The weaknesses of frequentism are in large part the weaknesses of the regularity theory of laws. An interesting objection with no parallel in the regularity account is as follows: In the case of reference classes containing countably infinite numbers of events, the value (indeed, the existence) of the limiting frequency will vary depending on how the outcomes are ordered. There appear to be no objective facts, then, about limiting frequencies. Or rather, if there are to be objective facts, there must be some canonical ordering of outcomes, either specified along with the reference class or fixed as a part of the scientific background. How serious an impediment this is to the frequentist is unclear.

THE PROPENSITY THEORY. If frequentism is the regularity theorist's natural interpretation of physical probability claims, then the propensity account is the interpretation for realists about laws, that is, for philosophers who believe that law statements assert the existence of relations of nomic necessity and causal tendencies (Armstrong 1983). For the propensity theorist, probabilities are propensities, and propensities are a certain kind of distinctly probabilistic causal tendency or disposition.

The propensity theorist's home territory is single-case probability, the kind of probability attached to a particular physical process or outcome independently of the specification of a reference class or ordering of outcomes. Because propensities are supposed to be intrinsic properties of token processes, on the propensity view every probability is a single-case probability. Given some particular outcome that one wishes to predict or explain, then, there is an absolute fact of the matter as to the physical probability of the outcome that one may—and presumably, must—use in one's prediction or explanation.

Of course, knowledge of this fact, if it is to be obtained by observing the statistics of repeated experiments, will require the choice of a reference class, the aim being to find a class containing processes that are sufficiently similar that their statistics reveal the nature of each of the underlying propensities in the class. Furthermore, by analogy with the case of deterministic causal tendencies, propensities may owe their existence to probabilistic laws governing classes of processes. Thus, something not unlike the frequentist's reference classes may turn up in both the epistemology and the metaphysics of propensities, but this does not detract from the fact that on the propensity view, there are real, observer-independent single-case probabilities.

To identify probabilities with propensities is revealing because one thinks that one has a good intuitive sense

of the nature of propensities in the deterministic case; one is reasonably clear on what it is to be fragile, aggressive, or paramagnetic. Though the metaphysics of dispositions is still a matter of dispute, it seems that one comes to deterministic propensities, at least at first, by grasping what they are propensities for: for example, breaking, violent behavior, and magnetic attraction. To adopt a propensity theory of probability, then, with the sense of familiarity the word *propensity* brings, is to make an implicit commitment to elucidating what probabilistic propensities are propensities for.

A straightforward answer to this question was given by Karl R. Popper (1959) in one of the earliest modern presentations of the propensity theory: A probabilistic propensity is a disposition to produce probabilistically patterned outcomes. A particular coin's probability for heads of one-half, then, is a disposition to produce a sequence of heads and tails that is disordered in the short term, but in the long term contains heads with a frequency of one-half. (Popper in fact omits the disorder requirement and allows that the sequence may be long and finite or infinite.) On Popper's view, then, a probabilistic propensity differs from a deterministic propensity not in the means of production, but only in what is produced: a probabilistic pattern over a long series of trials, rather than a single discrete episode of, say, shattering or magnetic attraction.

Popperian propensity theory is committed to the claim that, if the probability of a tossed coin's landing heads is one-half (and remains so), then continued tossing of the coin will eventually yield a set of outcomes of which about one-half are heads. But this sits badly with the intuitive conception of the workings of probability: If the probability of heads is one-half, then it is possible, though unlikely, that it will produce all heads for as long as one likes, even forever.

This intuition has an analog in probability mathematics. The law of large numbers prescribes a very high probability that the long-run frequency with which an outcome occurs will match its probability; by the same token, however, there is a nonzero probability that any (finite) long run will fail to produce a probability-matching frequency. There is some physical probability, then, that a probabilistic propensity will fail to produce what, according to the Popperian propensity view, it must produce. If this physical probability is itself a Popperian propensity—and surely it is just another manifestation of the original one-half propensity for heads—then it must produce, by Popper's definition, a matching frequency, which is to say that it must

occasionally produce the supposedly impossible series of heads. If it is to be consistent, Popper's definition must be carefully circumscribed. (There is a lesson here for frequentists, too.)

Most propensity theorists accept that probabilistic setups will occasionally fail to produce probability-matching frequencies. Thus, they repudiate Popper's version of the propensity theory. What, then, can they say about the nature of the propensity? Typically, they hold that the probability of, say, heads is a propensity to produce the appropriate probabilistic patterns with a high physical probability (Fetzer 1971, Giere 1973)—thus, such a probabilistic propensity is probabilistic not only in its characteristic effect, which is, as on Popper's definition, a probabilistic pattern, but also in its relation to the effect. (D. H. Mellor [1971] offers an interesting variant on this view.)

Whereas the Popperian definition comes close to inconsistency, this new definition is manifestly circular. Its proponents accept the circularity, so committing themselves to the ineffability of probabilistic propensities.

The ineffability of propensities, it is asserted, is not a problem provided that their values can be inferred; the usual apparatus of statistical inference is tendered for this purpose. Critics of the post-Popperian propensity interpretation naturally fasten on the question of whether it succeeds in saying anything substantive about probability at all—anything, for example, that illuminates the question of why physical probabilities conform to the axioms of the probability calculus or explain the outcomes that they produce. It does seem that modern propensity theorists are not so far from what is sometimes called the semantic interpretation of probability, on which probabilities are considered to be model-theoretic constructs that ought not to be interpreted at all, but simply accepted as formal waypoints between evidence and prediction in probabilistic reasoning (Braithwaite 1953). Compare Carnap's (1950) notion of partial interpretation and Patrick Suppes (1973).

A characteristic doctrine of the propensity theory is that probabilistic propensities, hence probabilities, are metaphysically irreducible: They are in some sense fundamental building blocks of the universe. The corollary to this doctrine is that the physical probabilities science assigns to outcomes that are deterministically produced—including, according to many philosophers, the probabilities of statistical mechanics, evolutionary biology, and so on—are, because they are not irreducible, they are not propensities, and because they are not

propensities, they are irreducible. Ronald N. Giere (1973) writes that they must be given an “as if” interpretation, but propensity theorists offer no account of “as if” probability’s scientific role.

On a broader understanding of the nature of a propensity, however, at least some of the physical probabilities assigned by science to the outcomes of deterministic processes might count as probabilistic propensities. As explained in the entry on chaos, certain subclasses of chaotic systems have dynamic properties in virtue of which they tend to generate probabilistic patterns of outcomes (Strevens 2003). These dynamic properties may be understood, then, as endowing the systems with a propensity to produce probabilistic patterns, and the propensity itself may be identified with the physical probabilities that science ascribes to the outcomes.

There is one, not inconsiderable, complication: The systems in question will generate the probabilistic patterns only given appropriate initial conditions. Almost all, but not all, initial conditions will do. This raises two important questions that need to be answered if chaos is to provide a part of the foundation for the metaphysics of physical probability. First, ought the necessary properties of the initial conditions to be considered a part of the propensity? If so, the propensity seems not to be an intrinsic causal property of the process. Second, the initial conditions are, in this context, most naturally described using a probability distribution. Thus, the basis of the probabilistic propensity is a further probabilistic element itself in need of analysis.

THE SUBJECTIVIST THEORY. It is something of a mystery why the mathematics of the probability calculus should be useful both for capturing elements of belief and inductive inference and for describing the processes that give rise to probabilistic patterns, or in other words, why two such different things as epistemic and physical probability should share the same formal structure.

According to the subjectivist theory of physical probability, there is no mystery at all: Physical probabilities are nothing but a certain kind of subjective probability. The intuition that, say, the probability of heads is a quantification of some physical property of the tossed coin is, on the subjectivist approach, an illusion: There are frequencies and mechanical properties out in the world, but physical probabilities exist entirely in the descriptive apparatus of people’s theories, or in their minds.

For the principal architect of subjectivism, Bruno de Finetti, the appeal of the theory is not only its neoclassical reunification of epistemic and physical probability but

also its empiricism: Subjectivism is most at home in what is now called a Humean world. Of course, frequentism is also a theory of physical probability that the metaphysical empiricist can embrace; the main advantage of subjectivism over frequentism is its provision—if such is truly necessary—of single-case probabilities (de Finetti 1964).

Subjectivism asserts the identity of the subjective probability for heads and the physical probability for heads. But it does not claim that, say, one’s subjective probability for the MACHO theory of dark matter is also a physical probability for the theory. Rightly so, because one does not acknowledge the existence of physical probabilities wherever there are subjective probabilities. A plausible subjectivism must have the consequence that one projects only a small subset of one’s subjective probabilities onto the world as physical probabilities.

At the heart of the subjectivist theory, then, must be a criterion that picks out just those subjective probabilities that are experienced as physical and that accounts for their particular, peculiar phenomenology. The key notion in the criterion is one of resilience: Unlike most subjective probabilities, which change as more evidence comes in, the subjective probabilities one calls physical have attained a certain kind of stability under the impact of additional information. This stability gives them the appearance of objectivity, hence of reality, hence of physicality, or so the subjectivist story goes. Brian Skyrms (1980) employs this same notion of resilience to give a projectivist account of causal tendencies and lawhood in the deterministic as well as the probabilistic case; subjectivism, then, like frequentism and the propensity theory, can be seen as a part of a larger project embracing all causal and nomological metaphysics.

There is an obvious difficulty with the subjectivist position as elaborated so far: My subjective probability for an outcome such as a coin’s landing heads may very well change as the evidence comes in. I may begin by believing that a certain coin is fair, and so that the physical probability of its yielding heads when tossed is one-half. As I continue to toss it, however, I may come to the realization that it is biased, settling eventually on the hypothesis that the physical probability of heads is three-quarters. Throughout the process of experimentation, I project (according to the subjectivist) a physical probability distribution onto the coin, yet throughout the process, because the projected physical probability for heads is changing, increasing from one-half to three-quarters, my subjective probability for heads is also changing. Where is the resilience?

De Finetti's (1964) achievement is to find a kind of resilience, or constancy, in my subjective probabilities even as my subjective probability for heads is changing. This resilience is captured by the property de Finetti calls exchangeability. Consider my subjective probability distribution over, say, the outcomes of the next four tosses of my coin. Every possible sequence of four outcomes will be assigned some subjective probability. The probability assignment—the subjective probability distribution—is said to be exchangeable if any two sequences having the same number of heads and tails are assigned equal probabilities. For example, exchangeability implies that HTHT and HHTT, each having two heads and two tails, are assigned the same probability, but allows this probability to differ from that assigned to, say, HHHT. In an exchangeable distribution, then, the probability assigned to a sequence of heads and tails depends only on the relative frequency with which heads and tails occur in the sequence (in the case of infinite sequences, which de Finetti uses in his mathematical construction, substitute *limiting frequency*).

If my subjective probability distribution over heads and tails is exchangeable, then the order in which the heads and tails come in as I experiment with my coin will not in itself affect my subjective probability for heads. The frequency with which heads and tails come in will, by contrast, most definitely affect my subjective probability. Thus, exchangeability is a kind of partial resilience; it is resilience to information about order, but not frequency.

De Finetti (1964) claims, uncontroversially, that one's subjective probability distributions over future sequences of heads and tails (and the outcomes of other Bernoulli setups) are exchangeable. He goes on to prove a theorem—his celebrated representation theorem—that shows that the following two reasoners will be outwardly indistinguishable: First, a reasoner who has various hypotheses about the physical probability of heads and updates the subjective probabilities for these hypotheses in the usual way as evidence comes in, and second, a reasoner who has no beliefs about physical probabilities, but simply has an exchangeable subjective probability distribution over future sequences of outcomes. The only difference between the two reasoners, then, will be that the first will claim, presumably as a result of introspection, to be learning about the values of physical probabilities in the world.

The subjectivist's sly suggestion is that people are all in fact reasoners of the second kind, falsely believing that they are reasoners of the first kind. Or, in a more revisionist mood the subjectivist may argue that, though they are reasoners of the first kind, they will give up nothing

but dubious metaphysical commitments by becoming reasoners of the second kind.

Critics of subjectivism question the aptness of exchangeability as a psychological foundation for probabilistic reasoning. The sole reason that people assign exchangeable subjective probability distributions to certain classes of sequences, according to these writers, is that they believe the sequences to be produced by physical probabilities (Bernoulli distributions, to be exact) and they know that an exchangeable subjective probability distribution is appropriate for outcomes so produced. Note that this argument has both a descriptive and normative dimension: Against a descriptive subjectivist, who holds that beliefs about physical probability play no role in people's probabilistic reasoning, the critic proposes that such beliefs cause them to assign exchangeable distributions. Against a normative subjectivist, who holds that beliefs about physical probability should not play a role in people's probabilistic reasoning, the critic proposes that such beliefs are required to justify their assigning exchangeable distributions.

A different line of criticism targets subjectivism's metaphysics: Why not identify physical probability with whatever produces the probabilistic patterns? Why not say that the probability of heads is a quantification of, at least in part, the physical symmetry of the coin? Such a position has its problems, of course, but they are not obviously insurmountable. More generally, given the rich array of options available for understanding the nature of physical probability, the subjectivist's flight from any attempt to give a metaphysics seems to many, as yet, insufficiently motivated.

PROBABILITY COORDINATION

It is generally accepted that it is rational, in normal circumstances, to set one's subjective probability for an event equal to the physical probability ascribed by science to that event or to that type of event. Returning to the first paragraph of this entry, if the physical probability of a hurricane is high, I should expect—I should assign a high subjective probability to—a hurricane strike. This is the principle of probability coordination.

Because the equation of physical and epistemic probability is made explicit in the classical definition of probability, classicists are probability coordinators par excellence. Leibniz, for example, articulates what appears to be an early formulation of the probability coordination principle when he writes “quod facile est in re, id probabile est in mente” (Hacking, 1975, p. 128); Ian Hacking glosses this as “our judgment of probability ‘in the mind’

is proportional to (what we believe to be) the facility or propensity of things” (the parenthesized phrase is not in the Latin; 1975, p. 128). But strictly speaking, of course, classicists cannot conceive of this as a coordination of different kinds of probability, since they allow only one kind of probability.

In the twentieth century, probability coordination was introduced as a topic in its own right by David Miller, who argued, as a part of a Popperian case against inductive inference, that a probability coordination principle would have to be inconsistent. Commentators soon pointed out that there are consistent versions of the principle, and some years later David Lewis wrote what is still the most influential paper about the proper form of a principle of coordination and its role in scientific inference, conjecturing that such a principle “capture[s] all we know about [physical probability]” (1980, p.266).

Modern attempts at a formulation of a probability coordination principle contain two elements not present in Leibniz’s maxim. First is the modification interpolated by Hacking: The principle commands that one sets one’s subjective probabilities equal not to the corresponding physical probabilities, but to what one believes the values of those probabilities to be, or more generally, to the mean of the different possible values, weighted by one’s subjective probability that each value is the correct one. Such a principle might be loosely interpreted as saying that one should do one’s best to set one’s subjective probabilities equal to the physical probabilities.

Second is a restriction of the range of the principle: When one possesses certain kinds of information, probability coordination is not necessarily rational. Suppose, for example, that I know for some science-fictional reason that the coin I am about to toss will land heads. Then I should set my subjective probability for heads equal to one, not equal to the physical probability of one-half. The information that the coin will land heads is what Lewis (1980) calls inadmissible information; in the presence of inadmissible information, the principle of probability coordination does not apply. Note that what is admissible is relative to the outcome in question; knowing how the coin lands is admissible when I am setting my subjective probability for the outcome of a different toss.

An attempt at a probability coordination principle might, then, have the following form: one’s subjective probability for an event e , conditional both on the proposition that the physical probability of e is p and on any admissible information k , should be set equal to p . (One’s unconditional subjective probability for e , then, will be the weighted sum of the physical probabilities, as men-

tioned earlier.) In symbols: If one’s background knowledge is admissible, then set

$$C(e|tk) = P_t(e),$$

where $C(\cdot)$ is one’s subjective probability distribution, t is the proposition that the correct physical probability distribution for e is $P_t(\cdot)$, and k is any other admissible information.

Note that propositions such as t are normally consequences of two kinds of fact: probabilistic laws of nature and some properties of e in virtue of which it falls under the laws. For example, if e is the event of a particular coin toss’s landing heads, then the law might be “All tosses of a fair coin land heads with physical probability one-half” and the additional fact the fairness of the coin in question. In what follows it is assumed that the latter facts are part of the background knowledge, and that t simply asserts some probabilistic law of nature, as suggested by the previous notation.

The most puzzling aspect of the probability coordination principle is the nature of admissibility. Lewis proposes a working definition of admissibility (he says that it is a “sufficient or almost sufficient” condition for admissibility) on which information is admissible either if it is historical—if it concerns only facts about the past up to the point where the principle is invoked—or if it is purely probabilistic, that is, if it is information about physical probabilities themselves.

The definition is problematic for two reasons. One difficulty is explicitly identified by Lewis (1980) and for many years prevented him from advancing the frequency-based theory of physical probability that he wished to give. As noted earlier, when coordinating probabilities for a given outcome, information about the future occurrence or otherwise of that outcome ought to be counted inadmissible. It turns out that frequency-based probabilities provide information of this sort. Lewis, then, has three choices. The first is to revise the working definition of admissibility so as to rule out such information, in which case information about physical probabilities will be inadmissible and the resulting probability coordination principle will be useless. The second is to stay with the working definition of admissibility, allowing the information provided by frequency-based probabilities to count as admissible by fiat. It can be shown, however, that the resulting principle—that is, Lewis’s original principle—clearly sets the wrong subjective probabilities in certain circumstances: There are certain complex facts about the future that a frequency-based probability distribution entails cannot

obtain, yet assigns a nonzero probability. If such a probability distribution is known to be the correct one, then the right subjective probability for the facts is zero, but probability coordination results in a nonzero subjective probability. The third option is to abandon probability coordination as such. Lewis takes the third way out, proposing a new kind of probability coordination principle that has the form (using the notation from earlier) $C(e|tk) = P_i(e|t)$. Michael Strevens (1995) points out that both Lewis's new principle and his original principle are consequences of a more general probability coordination principle according to which conditional subjective probabilities should be set equal to conditional physical probabilities. This principle yields Lewis's original principle when information about physical probability distributions is admissible and Lewis's new principle when it is not.

A different problem with Lewis's working definition of admissibility is that it makes no sense of probability coordination in deterministic systems. If one conditionalizes on the exact initial conditions of a coin toss, one ought not to set one's subjective probability for heads to the physical probability of heads, one-half, but either to zero or to one depending on whether those particular initial conditions cause the coin to land heads or tails. If a probability coordination principle is to be applied to the probability of heads, exact information about initial conditions must therefore be ruled inadmissible. Lewis's (1980) working definition of admissibility counts initial conditions, like all historical facts, as admissible.

Lewis (1980) does not regard this as a problem, since he agrees with the propensity theorists that in deterministic systems there could be only ersatz physical probabilities. Even if this is correct as a metaphysical doctrine, however, it remains a matter of fact that one coordinates one's subjective probabilities with such ersatz probabilities all the time, as when one forms expectations about the outcomes of a tossed coin. Whatever one calls it, then, there is a coordination principle for systems such as gambling devices that apparently has the same form as the genuine probability coordination principle (for a reconciliation of Lewis's account of physical probability and probability coordination in deterministic systems, see Loewer 2001).

There is clearly more work to be done elucidating the form of the probability coordination process, and in understanding admissibility in particular. A different project attempts to justify the practice of probability coordination, by giving an a priori argument that subjective probabilities should track physical probabilities, or

beliefs about such. Lewis himself says no more than that he can "see dimly" why probability coordination is rational. Howson and Urbach (1993) attempt a full-blown justification. Strevens (1999) argues that Howson and Urbach's argument appeals implicitly to a principle of indifference and goes on to make a case that there is a strong parallel between providing an a priori justification for probability coordination and providing an a priori justification for inductive inference, that is, solving the problem of induction.

A final question about the relation between epistemic and physical probability was adumbrated earlier: Why should the same formal structure be central to one's understanding of two such different things as the production of the probabilistic patterns and the nature of inductive reasoning?

PROCLUS

(412–485)

Proclus was born in Constantinople into a Lycean family that was still faithful to the old Hellenic religion in a society already dominated by Christianity. The talented young man forsook a career as a lawyer and decided to devote his life entirely to philosophy. After studies in Alexandria, he arrived in 431 in Athens where he joined the Platonic school of Syrianus. After the death of his venerated master, he became the leader of this school and remained in that position for almost fifty years until his death in 485. As we know from his biographer Marinus, his whole life was devoted to teaching and writing. Proclus was also a deeply devout person. In the community of the school he continued to practice with his disciples the rituals of the old Hellenic religion as well as the theurgical rituals of the Chaldeans. For Proclus, Plato was more than a philosopher intent upon the search for the truth; he was also a divinely inspired prophet showing the soul a way of salvation. Reading Plato had become more than just a scholarly exercise—it was a religious activity of paramount importance.

Proclus was convinced that the truth had been revealed by the gods in many different ways, in obscure oracles, myths and symbols. He saw himself as the interpreter whose task it was to explain the hidden significance of those religious traditions in a civilization where they were doomed to disappear. It was his ambition to prove the harmony between Plato and the other sources of divinely inspired wisdom, in particular the Chaldean Oracles and the Orphic poems. In his view, only a philosophical approach could offer the framework and rational arguments needed for this interpretation. For that reason Plato remained for him the ultimate authority in all matters, divine and human. Aristotle, on the contrary, was given only a subsidiary role, as he never developed a proper theology. His significance was restricted to matters of logic and physics.

Proclus wrote commentaries on the dialogues of Plato that were part of the curriculum of the Neoplatonic school. The course started with the reading of the *Alcibiades I* about self-knowledge, which was regarded as an introduction to philosophy, and culminated in the explanation of the two major dialogues of the Platonic corpus: the *Timaeus* about the generation of the physical world and the *Parmenides*, which was thought to offer Plato's doctrine on the first principles. Proclus also wrote a series of interpretative essays on the *Republic*. The commentaries of Proclus are masterpieces of their genre: They not only

offer a systematic interpretation of the text, but also introduce his own philosophical views and provide us with a wealth of information about the discussions within the Platonic tradition. That is particularly the case with the commentary on the *Timaeus*: Proclus defends Plato's explanation of the physical world as superior to that in Aristotle's *Physics* because only Plato discovered the ultimate (i.e., divine) causes of the physical phenomena.

Besides his work on Plato, Proclus composed a remarkable commentary on Euclid's *Elements*, the prologues of which offer a philosophical introduction to the study of the mathematical sciences. The *Hypotyposis*, or *Outline of the Astronomical Hypotheses*, is another indication of his interest in science and cosmology. Proclus also wrote short treatises on diverse subjects, such as the treatise *On the Existence of Evils*, in which he attempts to explain the existence of evil in a world proceeding from an absolutely good principle. If all agents act for some good and yet, evil occurs, it is unintended and uncaused. Evil cannot exist in its own right and no proper cause explains it. Its existence is parasitic (*para-hypostasis*), supervening upon substances and acts. This doctrine, which was adopted by a Christian author writing under the pseudonym of Pseudo-Dionysus in his celebrated treatise *On the Divine Names*, became for centuries the dominant view in philosophical and theological debates on evil.

Besides his commentaries, Proclus owes his reputation to his two great syntheses of Platonic philosophy, the *Elements of Theology* and the *Platonic Theology*. Theology is for Proclus a rational investigation into the first causes and principles of all things. The first philosophers only admitted corporeal entities, such as fire or water, as first causes. Later philosophers recognized souls as principles of life and movement and thus discovered noncorporeal being. Aristotle posited unmoved intellects above the self-moving souls and considered the first intellect to be the ultimate divine cause. Only Plato, however, recognized a cause beyond intellect, beyond being, beyond knowledge and discourse, namely the One, from which all things including matter derive their existence (*Platonic Theology* I,1). Therefore, Plato's theology is for Proclus (and for the entire Neoplatonic school since Plotinus) the accomplishment of all preceding theological speculation, since it reveals the "three principal hypostases": the One, the Intellect, the Soul.

ELEMENTS OF THEOLOGY

In this work, the metaphysical counterpart of Euclid's *Elements*, Proclus demonstrates "in a geometrical manner" the

most fundamental theorems of the theological or metaphysical science as he understands it. The work contains 211 propositions, each of them followed by a demonstration. The first part (props. 1–112) examines the fundamental principles that govern the structure of all reality, such as the relation between the One and the many, the cause and the effect, the whole and the parts, transcendence and participation, procession and reversion, continuity and discontinuity, Being, Life and Intellect, limit and limitedness, self-movement and self-constitution, act and potency, eternity and time.

In the second part (props. 113–211) Proclus gives a survey of all degrees of reality, applying to them the general metaphysical principles he had demonstrated before. He discusses successively the gods (or "henads"), the intellects and the souls. The physical realm falls outside the scope of this theological metaphysics. The *Elements of Theology* is without doubt the most original work of Proclus, not so much because of its content (which offers the standard doctrine of the Athenian school), but because of its extraordinary attempt to develop the entire Neoplatonic metaphysics from a set of axioms. It also had a tremendous influence, in particular through the Arabic adaptation that was made in the ninth century in the circle of Al-Kindī. In the middle of the twelfth century this Arabic treatise was translated into Latin. The *Liber de Causis*, as it was named, circulated as the work of Aristotle and thus obtained a great authority in medieval Scholasticism. The systematic character of the *Elements* and its rigorous method make it for the student the best introduction to the complicated thought of Proclus.

ONE AND MULTIPLICITY. The *Elements* begin with the proposition that "every manifold in some way participates in unity." Without some form of unity a multitude would fall apart into an infinity of infinite things. A multitude cannot, however, be itself the unity it participates in. It is not the One, but a unified manifold, having unity as an attribute, and is therefore posterior to the One itself upon which it depends. All things, then, derive their being ultimately from the One from which they proceed.

This One must be identified with the Good, since it is the proper function of the One to hold together all things and maintain them in existence, which is also the function of the Good. For to hold a thing together and make it one is to give it its perfection and well-being, whereas dispersion is the cause of its destruction and evil. Since the Good is what unifies things and the One is what gives them perfection, the One and the Good are names

designating the absolute principle from which and toward which all things eternally proceed and return.

Having demonstrated the necessity of the One as the first principle, Proclus explains how all things in all their specificity proceed from this One. It is impossible to admit that the utmost multiplicity of the material world with its particularized bodies would proceed immediately from the first principle. Plotinus had already argued that from the One comes first the Intellect and from the Intellect proceeds the Soul, which stands itself at the beginning of time, division, and movement. For Proclus, this Plotinian understanding of the procession is unsatisfactory, in particular with regard to the second level, the Intellect, which is identical with true Being and Life. If we respect the “law of continuity,” which governs the procession of all things along the “chain of being,” we cannot admit that the Intellect (which contains already the Forms of all things) comes into existence immediately after the absolute One. There must be “mean terms” connecting the extremities. From the One comes forth Being, from Being Life, from Life the Intellect. Whereas Being is the ultimate intelligible object (*noēton*), the Intellect, which contains in its thought the paradigmatic Forms, is the properly intellectual level (*noeron*). The intermediate realm of Life is the intelligible-intellectual. In this triad of hypostases, the superior level has the most comprehensive and farthest reaching causality: for all things participate in being, but not all are living or capable of thinking. The causality of the One reaches even further than that of Being, since matter, the indeterminate substrate of the physical realm, does depend on the One, though it does not really “exist.”

THE TRIADIC DYNAMIC STRUCTURE OF REALITY. Many propositions in the *Elements* concern causality (hence the Latin-Arabic adaptation is appropriately called *De causis*): they are not about the physical causes, which are for Proclus only auxiliary causes, but about the “true causes,” which always transcend their effect. Whatever produces something must be superior to the effect, which owes its existence to it. If this effect has itself the power to produce, it will produce again something inferior to it, until the procession comes down to what is altogether unproductive, that is, matter. Although the effect is inferior to its cause, it is also somehow similar to that which has produced it. The effect is in a secondary manner what its cause is primarily. Insofar as the effect is similar to its cause and shares its character, it is said to “remain” in its cause without yet having its proper existence. On the superior level, it exits “causally” or “potentially” (if “potency” is understood as a productive power).

A being only acquires its proper existence (*hyparxis*) when it proceeds from its cause and becomes distinguished from it. Through the procession it becomes somehow dissimilar to the cause. Yet the procession from the cause cannot go on infinitely: the effect must also revert upon the cause from which it proceeds. Through this “return” (*epistrophē*) the effect strives to be connected again with its cause and becomes similar to it. If things have their being through procession, they attain their well-being or perfection through reversion. For the cause of their well-being can only come from the origin of their being. The final cause is thus identical with the efficient, since all things desire as ultimate end that which is the principle of their procession. As Proclus formulates it: “All that is produced by a cause both remains in it and proceeds from it” (*Elements of Theology*, § 30). “All that proceeds from something reverts upon that from which it proceeds” (§ 31). Therefore, “all that proceeds from a principle and reverts upon it has a cyclical activity” (§ 33). All beings remain in their causes, proceed from them, and return to them, in an eternal circularity, since the end is identical with the origin. Proclus finds this triadic dynamic structure on all levels of reality.

PARTICIPATION AND NONPARTICIPATION. When attempting to understand the relation between the Forms and the many things that are similar to them, Plato introduced the metaphor of “participation.” Participation, however, raises as many problems as it solves, as Plato shows in the aporetic discussion of the *Parmenides* (which offered ammunition for Aristotle’s subsequent criticism). The term seems to suggest that the many things sharing in the same Form take “parts” of it. How can one reconcile the transcendence of the Forms with their presence in the many things? If participation is real, the Forms must be immanent in the things sharing them and hence will be divided. But how, then, can the transcendence of the Forms be preserved? If, on the other hand, we stress the unity and the indivisibility of the Forms, we end up making participation impossible.

Proclus’s solution to this problem is the distinction between the participated and unparticipated mode of a *hypostasis*. What is participated in by the particular things cannot be the ideal Form itself, but must be a form that comes forth from it and is present in them. These immanent forms are somehow comparable to the Aristotelian Forms in matter. However, whereas Aristotle rejects the transcendent Forms as an unnecessary duplication of reality, Proclus argues that the unparticipated Forms are necessary to guarantee the universal character of the forms in matter. The participated form belongs entirely

to the particular thing sharing it. Since what inheres in one thing cannot be present in another, there is no explanation of the fact that the many things, though obtaining a proper form, have this form in common. By postulating an unparticipated Form, which exists prior to all participated forms proceeding from it, the Platonists can explain how the *eidos* is common to all that can share in it and nevertheless the same in all. As is said in proposition 23: “all that is unparticipated brings forth from itself the participated; and all the participated hypostases extend back to the unparticipated.”

The distinction between the participated and the unparticipated not only applies to the Forms, but to all levels of reality: Soul, Intellect, and even the One. Within each realm a distinction must be made between the first unparticipated term (the “monad”) and the “series” or multiplicity of beings of a similar nature coordinated with it. Thus, besides the many souls that are participated in on various levels by different bodies—the particular souls by which each human being exists as a particular animal, the souls of demons, the planetary divine souls—we must postulate the existence of the unparticipated Soul, from which a multiplicity of souls proceeds according to diverse modes of participation.

Similarly, besides the many particular intellects participated in by different divine and human souls, there must also exist an absolute unparticipated Intellect, which comprises the totality of all Forms. The many intellects proceed from this absolute Intellect and form together with it a coordinate series of a similar intellectual nature. Following the same line of reasoning, we must also posit after the One, which is absolutely transcendent and can in no way be participated by the inferior levels, a manifold series of “ones,” “units,” or “henads” consequent upon the primal One, which are participated in by the different classes of being. Those henads are not the modalities of unity acquired by beings, but self-subsisting units which remain transcendent above the beings that depend upon them. Though they are in themselves beyond being and beyond knowledge, as is the primal One, in which they remain co-united, their distinctive properties can be inferred indirectly from the different classes of beings dependent upon them. “For differences within an order of participants are determined by the distinctive properties of the principles participated in” (*Elements of Theology* § 123).

In view of the different classes of beings depending upon them, we can distinguish, for example, intelligible, intellectual, hypercosmic, or encosmic henads. Yet, insofar as they are all self-subsisting units, they remain uni-

fied in the One itself. If the One stands for the first divine cause, the different henads constitute the different classes of the gods. “For every god except the One is participable” (§ 116). With this doctrine of the henads, Proclus can defend—against Christian monotheism—both the unity and multiplicity of the divine. In his view, it is the main task of a Platonic philosopher to explain in a rational system the procession and the distinctive properties of all the classes of the gods we know through the diverse religious traditions. That is the purpose of Proclus’s last magnum opus.

THE PLATONIC THEOLOGY

Proclus distinguishes four types of theological discourse. Divinely inspired poets use dramatic stories (talking about sexual relations, births, fights, cuttings of organs) to symbolically indicate the processions of the divine principles and their mutual relations. This mythological discourse is characteristic of the ancient Hellenic theology, as known through the Orphic poems and the works of Homer and Hesiod. In oracular discourse (in particular the *Chaldean Oracles*) prophets reveal the names and properties of the gods without resorting to the dramatic scenery of mythology. The Pythagoreans resort to mathematical analogies and similitudes (numbers, circles, spheres) to disclose the divine orders. Finally, there is scientific or dialectical theology, which investigates the divine classes and their properties using strictly rational arguments and an abstract philosophical vocabulary: one and many, being, whole and part, identity and otherness, similarity and dissimilarity.

This scientific theology has been brought to perfection by Plato in his dialogue *Parmenides*. In Proclus’s interpretation, this dialogue displays the fundamental axioms and basic concepts needed for the development of a scientific theology. In the second part of this dialogue, Parmenides examines in a dialectical exercise the hypothesis of Unity, considering the consequences following from the position of the One and from its denial, both for the One and for what is other than the One. If we start from the hypothesis of the One, only negative conclusions seem to follow: the One has no parts and is not a whole; it is not in something nor in itself; it is neither similar nor dissimilar. One cannot even say that it “is” or “is one.” In short, no names, no discourse, no knowledge of it is possible. Parmenides therefore has to restate his original hypothesis, now emphasizing the existence of the One. All attributes that were denied in the first hypothesis can be predicated of this One-that-is.

The interpretation of the different hypotheses of the *Parmenides* (of which we mention only the first two) led to a lively debate in the Neoplatonic school, as we know from Proclus's commentary. Proclus defends a theological interpretation of this dialectical discussion about the One and the Many. If the "One" stands for the first principle, the successive hypotheses of the *Parmenides* must refer to the different principles of the whole of reality. The One of the first hypothesis, of which no discourse is possible, is the absolute, unparticipated One or primal god. In the second hypothesis, Parmenides deduces, through the subsequent conclusions following from the position of the One-that-is, the different modes of unity ("henads") that are participated in by the different degrees of being. Whereas the first hypothesis leads to a negative theology, the deductions from the second hypothesis give the articulations of a positive theology. "In this dialogue proceed all the divine classes in good order from the first cause and demonstrate their mutual connection" (*Platonic Theology*, I, ch. 7).

When interpreted in this way, the *Parmenides* provides a framework in which the other discourses about the gods can be integrated and decoded: the mythological stories about Zeus and Kronos from the Hellenic and Orphic traditions, the strange divine names revealed in the *Chaldean Oracles*, the mathematical *theologumena* of the Pythagoreans, the various scattered remarks about the gods in the other dialogues of Plato. In the Renaissance, Marsilio Ficino adapted the model of Proclus's theology in an original way to integrate the revealed truth of Christianity.

CONCLUSION

It is difficult to evaluate the originality of a thinker who, in most of his works, claims to be nothing but a faithful follower of his master Syrianus. It is Proclus, however, who put his mark on the development of the later tradition of Neoplatonism in Byzantine, Arabic, and Latin medieval thought. His huge influence—much greater than that of Plotinus—is to be explained mainly by two important indirect channels: the Christian reception of his theology by Pseudo-Dionysus and the Arabic adaptation of the *Elements* in the *Liber de Causis*. And yet it is no historical accident that Proclus gained this fame. The *diadochos* (or successor) of Plato, as he was named, has been the authoritative commentator of Plato and the great systematizer of Neoplatonic metaphysics.

PRODICUS OF CEOS

Prodicus of Ceos, the Greek Sophist, was probably born before 460 BCE and was still alive at the time of the death of Socrates in 399 BCE. He traveled widely as an ambassador for Ceos and also earned a great deal of money lecturing in various Greek cities, especially in Athens. His writings are known to have dealt with physical doctrines,

with religious and moral themes, and above all with distinctions between the meanings of words usually treated as synonyms. Socrates attended a lecture by him on the last of these topics and regularly claimed to be a pupil of Prodicus in the art of synonymy (*Protagoras* 341A, *Meno* 96D).

In physics he appears to have treated the four elements of Empedocles as divine, and no doubt they formed the basis of the cosmology of Prodicus, to which Aristophanes refers in the *Birds* (1.692), although the fanciful cosmology that follows is probably not based on that of Prodicus. Prodicus further held that those natural objects and powers that are useful to human life were made the objects of cult and treated as gods by men. Inevitably, he was later classed as an atheist, but it is more likely that he offered an account of the origin of the gods that was not intended to deny their existence.

In a work titled the *Horae* (Hours) he included the since famous story “Heracles Where the Road Divides,” of which we have a fairly full summary in Book II of Xenophon’s *Memorabilia*. Vice and Virtue appear to Heracles personified as women and invite him to choose between them. Each describes what she has to offer, and Heracles chooses the arduous tasks of Virtue rather than the pleasures of Vice.

Of greater philosophic interest is the ethical relativism attributed to Prodicus in the pseudo-Platonic dialogue the *Eryxias*. There he is apparently quoted as arguing that what is good for one man is not good for another man, so that we cannot speak of anything as good *simpliciter*. On the other hand, the goodness of a thing does not depend on the goodness of the user (although some scholars have interpreted him this way). Rather, the value of a thing inheres in the thing itself in such a way that it will be good in relation to one person and not good in relation to another, according to the person and the way in which it is used.

The discussion of synonyms and the right use of words clearly involved fine distinctions of meaning between words. Many examples quoted are ethical, and a term of narrower application is commonly distinguished from one of wider application that includes in its range of meaning the meaning of the first term. The value of such distinctions is clear in rhetorical argument. But Prodicus was also eager to reject the kind of view found in Democritus, according to which there can be different names for the same thing since names are attached to things by convention only. Prodicus maintained, it would seem, that no two words have the same meaning, and in this he at least prepared the way for the search for precisely stated meanings that later fascinated Socrates and Plato.

PROGRESS, THE IDEA OF

In broad terms a popular belief in “progress” means the rejection of an attitude that has characterized most human communities throughout history. Normally, people have believed that the future would repeat the past. When they have expected that human life was going to change, they have usually supposed that this change was going to take place suddenly and radically, by supernatural intervention. And if they have permitted themselves to hope for the improvement of the human condition, the hope has commonly been directed toward salvation from the world rather than reform of the world. By and large, historical change, when people have been aware of it at all, has been viewed as a sign of mortality and the proof of a lapse from ideal standards. Indeed, in many societies there has been a popular conviction that humankind’s condition has changed in the course of history but for the worse. Characteristically, when people have believed in a golden age, they have put that age in the past rather than the future.

In contrast, in modern Western societies change and innovation have a different place in the popular imagination. Not everyone assumes that all change is necessarily for the better, but it is widely assumed, even by conservatives, that only a society that has a general capacity to change is capable of surviving. And despite wars and depressions a large proportion of the members of Western societies have tended to expect that, short of a cataclysm, their children would live happier and better lives

than they. They have supposed that this improvement would be cumulative and continuing and that although temporary setbacks, accidents, and disasters might take place, human knowledge, power, and happiness would increase over the long run.

The emergence of this idea is the product of a variety of circumstances, such as the accumulation of an economic surplus, the increase of social mobility, and the occurrence of major inventions that have dramatically increased human power over nature. Over and above these, however, the idea of progress is peculiarly a response to the emergence of the unique social institution of organized scientific inquiry.

HISTORY OF THE IDEA

Seeds of the faith in progress can be found in the works of the two great spokesmen for the new science, Francis Bacon and René Descartes. The fundamental elements of the idea itself were developed in the course of the so-called quarrel of the ancients and the moderns, which occupied writers and critics in the last part of the seventeenth century. At the heart of this controversy was a dispute over the authority that should be attributed to the opinions and examples left by the ancient writers. Was it the task of scholars to stand as sentinels at the gate, guarding against innovation and protecting established styles and beliefs? The controversy implicitly raised not only literary questions but the larger question of what attitude toward the past should govern the intellectual life.

In developing their position, the moderns argued that the partisans of the ancients were misled by a false analogy. They looked upon the ancients as their forefathers and therefore thought of the ancients as older and, in consequence, wiser than themselves. But just as the individual grows older and presumably wiser as time goes by, so does humanity. The so-called ancients were really the young men of humanity, and those alive today were the true ancients. They stood on the shoulders of their predecessors and could see farther; their wisdom and authority was greater than the wisdom and authority of their predecessors. This argument was developed with particular force by Bernard de Fontenelle in his *Digression sur les anciens et les modernes* (published in 1683).

The analogy between the history of humankind and the life of an individual had already been developed, however, by a number of writers. Blaise Pascal, for example, used it in drawing a belief in intellectual progress from an examination of the nature of scientific inquiry. In 1647, Pascal had published a study, *Nouvelles expériences*

touchant le vide, which encountered immediate objections from many scientists and philosophers, including Descartes, on the ground that it denied the time-honored truth that nature abhorred a vacuum. Pascal replied to one of his critics, Father Noel, that an appeal to inherited authority had no force where the study of physics was concerned. And in a longer essay, *Fragment d'un traité du vide*, he went on to give general reasons for moderating the respect for received authority. "The experiments which give us an understanding of nature multiply continually," he pointed out, "from whence it follows ... that not only each man advances in the sciences day by day, but that all men together make continual progress in them as the universe grows older." Pascal believed, however, that such progress took place only where the experimental methods of the sciences were relevant. In theology received authority set the final limits to inquiry, for there the object was not to add to the knowledge provided by ancient authority but only to understand as fully as possible what that authority revealed.

During the eighteenth century, however, and particularly in France an increasing number of intellectuals came to believe that the methods and spirit of science should be applied to all fields. In consequence, the idea of progress came to include a concept of social and moral progress. The cumulative improvement in human knowledge and power that had been brought about in the physical sciences could also be brought about in the organization of human society and the character of human conduct, it was asserted, if only the barriers that existed against the employment of rational methods in morals, religion, and politics could be removed. The Encyclopedists, chief among whom were Denis Diderot and Jean d'Alembert, led in the dissemination of this point of view. The most complete and moving expression of this faith in progress was the Marquis de Condorcet's *Esquisse d'un tableau historique des progrès de l'esprit humain*, written in 1793.

In the nineteenth century a new kind of historicist philosophy emerged that rejected the eighteenth-century conception of reason and the sharp dichotomy between the present and the past that had been made by believers in progress. This philosophy, best represented by G. W. F. Hegel, substituted the view that history followed its own inherent course of development and that this course of development embodied rational principles higher than those of merely human reason. Since this form of historicist philosophy identifies all conceivable changes as elements in an unfolding rational purpose, it deprives the idea of progress of definite meaning.

The more definite and combative eighteenth-century conception of progress, however, also continued to be a central theme in the thought of the nineteenth century. In one form or another, major figures of the century, such as Karl Marx, Auguste Comte, and John Stuart Mill, all propounded the doctrine. Although Marx, Comte, and Mill were influenced, each in his own way, by historicist ideas, each retained the characteristic eighteenth-century emphasis on the struggle between reason and superstition, on the movement of humankind away from theological and metaphysical modes of thought to positive or empirical habits of mind, and on the importance of extending the standards and methods of the sciences to all domains.

In the twentieth century the idea of progress continued to have adherents, particularly among American pragmatists, Marxists, and logical empiricists. For obvious historical reasons, however, advocates of the belief in progress have become steadily more modest in their claims since World War I, and since the turn of the twentieth century the idea of progress has been seized on by an increasing number of philosophers, theologians, and social critics as the prime fallacy of the tradition of liberalism and rationalism.

ANALYSIS OF THE IDEA

In tracing the history of the idea of progress, it is useful to distinguish between two motifs. Generally speaking, the belief in progress has been supported by an appeal to the progress of the sciences. In many cases, however, this appeal has consisted in showing that the sciences—usually some particular science—had uncovered fundamental truths that had been previously unknown and that progress would now take place if only these truths were accepted as guides to practice. Thus, progress has been said to be guaranteed if people lived by the fundamental principles disclosed by the science of economics, if they accepted the laws of historical development revealed by a scientific approach to history, or if they extended to the government of human society the Darwinian doctrine of evolution by natural selection. Progress has also been thought to be guaranteed if people could only come to recognize certain rational moral principles, such as universal natural rights. Such universal principles, though antecedent to any particular science, were nevertheless closely identified with science, for it was assumed that their validity would be apparent to anyone who could disengage himself from the superstitions and prejudices of the past and that this process of disengagement was immensely accelerated by the advent of science. This con-

ception of the nature and conditions of progress lends itself to Utopian and Messianic interpretations of progress when understood as an ideal but to the reduction of the idea, in G. M. Young's phrase, "from an aspiration to a schedule" when associated with rigid, a priori approaches to the problem of improving the human condition.

A second motif in the theory of progress, however, has associated progress not with any particular discoveries of science or reason but with the unique, self-corrective methods of science. From this point of view the essential conditions for progress are the rejection of absolutes and fidelity to the principles of free, fallibilistic, experimental inquiry in all domains of thought and action. Even if we assume that it is valid to assert that the methods of science are universally applicable, this approach obviously imposes practical conditions for progress that are immensely difficult and perhaps impossible to realize. Accordingly, those who adopt this approach to the idea of progress can be taken to be saying only that there is a possibility of progress or, at best, a slow and uneven historical tendency that is characteristic only of societies possessing an appropriate ethic and social order and whose continuation is by no means ensured. In the past many proponents of the idea of progress undoubtedly underestimated the difficulties of domesticating within society at large the attitudes and habits of mind exemplified in scientific investigation. Nevertheless, insofar as their concept of progress depended simply on an appeal to the character of scientific procedure, they cannot be said merely to have offered a secularized version of older religious beliefs in a heavenly city, and criticisms of them for having done so, which are standard in much of the literature related to the history of the idea of progress, are a source of considerable confusion.

To be sure, the theories of progress that were developed in the eighteenth and nineteenth centuries are often based on a combination of these two motifs. In Condorcet's thought, for example, there can be found Utopian as well as realistic formulations of the idea of progress. Nevertheless, it is a mistake, on the whole, to associate the idea—particularly as it arose in eighteenth-century France—with the naive hope that human beings and human society could be made perfect. If we study the specific predictions that Condorcet made with regard to the future of humanity, for example, we find that he pointed ahead, with extraordinary prescience, to what are now such commonplace facts as the lengthening of life expectancy, social insurance, and the guarantee of equal

legal rights to all citizens. Although none of these has brought the happiness and general reasonableness that Condorcet assumed they would, it was historical realism on his part, not juvenile innocence, to make such predictions. An inability to imagine the wretchedness of the past, not a cold, unillusioned understanding of the present, lies behind the failure to appreciate why reasonable men in the eighteenth and nineteenth centuries should have been rhapsodic about the possibility of changes in the human condition that, in the light of contemporary heightened expectations, may tend to appear fairly modest.

SCIENTIFIC PROGRESS. What can be said with regard to the validity of the idea of progress? We must first ask what meaning can be assigned to the notion of scientific progress.

One frequent argument against the validity of the belief in scientific progress is that it contains a self-contradiction. The belief that there is scientific progress is usually attached to the argument that science is continually self-corrective. But if science never does anything but correct itself, is there any sense in speaking of scientific progress? Does not the concept of progress presuppose a fixed end or standard, and does not science, at any rate as interpreted by those who emphasize its fallibilism, deny that there can be fixed ends or standards? *Progress*, in short, appears to be a term without meaning, according to this view, unless it can be attached to metaphysical standards, such as absolute truth, whose status is antecedent to science.

This view fails, however, once it is recognized that progress can also refer to the solution of particular problems, not only to the movement toward a general and abstract goal. For example, meaning can obviously be assigned to the statement that science has made progress in determining the causes of malaria or in describing the characteristics of the other side of the moon. Such statements mean that there are now answers to questions to which there were no answers before and that these answers are in accord with the procedures of inquiry in force among competent scientific investigators. Once scientific progress is defined in terms of the solutions to particular problems, sense can also be given to the notion of cumulative scientific progress, for the general scientific capacity to solve problems has also tended to grow.

Some doubt has been thrown on these conclusions, however, by recent philosophers of science. Karl Popper, for example, argued that scientific theories and hypotheses are never genuinely confirmed but at best succeed

only in resisting successive efforts to falsify them. Since the capacity of a scientific conclusion to survive a series of such efforts does not prove that it will always be able to do so, it would seem to make no sense to speak of successful or true solutions of scientific problems. Popper's view, however, seems to involve an unnecessarily paradoxical way of stating the truism that all scientific conclusions are subject to correction in the future. The survival of a scientific conclusion despite successive efforts to overthrow it adds to the degree of reliability that may reasonably be ascribed to it. It is just as possible to describe the critical position of scientists toward accepted conclusions as efforts to extend the range and reliability of these conclusions as it is to describe it as the expression of a compulsion to destroy what has been inherited. The accumulation of increasingly well-tested and continuously powerful ideas by the sciences is an obvious fact of their history, but as seen by Popper, it seems almost an accidental by-product.

Doubt has also been thrown on the belief in scientific progress by the view that the history of science is the record of revolutions in scientific theory so radical in character that it is impossible to establish the continuity between the ideas of one generation and the ideas of a later one. If this were true, it would be impossible a fortiori to establish a concept of progress, since such a concept presupposes a measure of continuity in the sequence of events under examination. Underlying this view is the thesis that the confirmation by experiment of particular hypotheses always entails the use of a specific theoretical framework. When this theoretical framework changes, observations are simply run through a different set of conceptual categories. Accordingly, it makes little sense, it is argued, to say that the sciences have improved or extended their knowledge, for all that has happened is that one body of beliefs has been substituted for another. This point of view raises epistemological and methodological questions of great complexity, and there is no room to discuss them sufficiently here. It appears to leave out of account, however, the consideration that, for example, fundamental principles of Newtonian physics can, with appropriate modifications, be absorbed into modern physical theories. It also appears to underestimate the implications of the fact that these principles, without substantial modification, continue to provide reliable instruments for the explanation and prediction of events in large sectors of macrophysics.

SOCIAL AND MORAL PROGRESS. Assuming that both meaning and truth can be assigned to the idea of progress in science, what is the status of the belief in social and

moral progress? Obviously, the answer to this question depends in part on the standards employed as the touchstones of progress. However, some of the difficulties involved in stating and defending such standards can be circumvented if in this sphere we also define progress in terms of the successful solution of specific problems. Thus, there has been striking progress in the control of disease, in methods of farming, in material productivity, in the reduction of backbreaking labor, in the techniques of rapid mass communication, in the spread of literacy, and probably in the reduction of the amount of violence in everyday life.

Of course, it is theoretically possible to hold a moral code from whose standpoint one or more of these historical trends would be regarded as retrogressive rather than progressive. In fact, however, even though members of different contemporary cultures (and members of the same culture) hold widely disparate moral outlooks, there are few informed and disinterested observers, whatever their moral outlooks, who regard any of these trends, considered in themselves, as movements in the wrong direction. And most would also look upon many other historical trends that have characterized the modern world—for example, the development of more humane attitudes in penology, the abolition of slavery and serfdom, the spread of the doctrine of basic human rights—in a similarly favorable light. To this extent it is possible to speak with a measure of precision and truth of social and moral progress.

But this answer, of course, goes only part of the way. On at least two scores it is incomplete. First, it is reasonable to ask whether the gains that have been mentioned have not been bought at a cost that more than cancels them out; second, it is possible to ask how we are to vindicate the moral principles in terms of which we assess these gains as gains.

The cost of progress. It is not possible, of course, to give a wholly unequivocal answer to the question of the cost of progress. The notion that large-scale historical trends can be neatly categorized as good or bad belongs to eschatology, not to mature historical analysis. If the reduction of civil violence, considered in itself, is a progressive trend, contemporary mass warfare and genocide must be considered retrogressive; if rapid mass communication is a benefit to humankind, the use of the facilities of communication for totalitarian thought control is a calamity. Moreover, the successful solution of many problems often creates new and more difficult ones. The control of disease, for example, has created a serious threat of overpopulation. And by what calculus can one

measure the gains brought about, for example, by industrial innovations against the losses brought about by mass warfare or cyclical unemployment? A moral accounting system for judging even much simpler matters than these does not exist.

Nevertheless, if the span of time we measure is sufficiently long, it remains true that on the whole the physical lot of most ordinary people has considerably improved in modern societies and that this has largely been due to the application of rational techniques to the economy. The cost has been grievous, and many of the sacrifices this progress has entailed could probably have been avoided if people had employed reasonable forethought and had shown reasonable respect for the equities. Admittedly, too, it is difficult to say whether this physical progress has made individuals “happier”; indeed, it is doubly difficult to say this, for “happiness” is in part a function of what people expect, and physical progress has meant an enormous expansion of their expectations. Nevertheless, it is doubtful that most of those who put forward the view that the costs of material progress outweigh the benefits would willingly exchange places with any but the most privileged members of past societies if they actually had the chance.

Nor must we confine ourselves to a belief in purely physical or material progress. The role of fantasy, ignorance, superstition, and fanaticism in determining the world’s affairs continues to be enormous. It is doubtful, however, whether so many members of human societies, from housewives to statesmen, have ever before thought it reasonable to make decisions on the basis of carefully acquired and sifted information, and never before have societies possessed as much knowledge about themselves and their workings as they do now, shaky and scattered though that knowledge is. Only if one thinks it morally dangerous to seek reliable information before making decisions or thinks it mistaken to try to employ rational methods in the study of human affairs can he declare such long-range social trends to be anything but progressive. Indeed, the very reason that the members of an educated modern society bear a particularly heavy burden of responsibility for the emergence of doctrines such as Nazism is that they have opportunities to be informed and judicious which members of other societies did not have. In sum, although it is not possible to say in wholesale terms that there has been moral progress, it is possible to assert that the context of human behavior has changed and that the collective capacity to achieve human purposes, whether good or ill, has enormously increased. The expectations that it is reasonable to

impose on modern social arrangements are therefore justifiably higher than those that may have been reasonable in the past. In this modified but important sense it is fair to speak of moral progress.

Justification of moral standards. All the preceding reflections, however, obviously presuppose the validity of a secular, liberal, and rationalistic moral code. In the end, as must be obvious, objections to the idea of progress usually turn on fundamental differences in values. Whether the validity of one fundamental moral outlook as against another can be demonstratively proved is an issue that falls beyond the scope of the present article. If we assume, however, that we cannot resolve these differences in a way that will satisfy traditional standards of demonstrative certainty, there is no so-called ultimate answer to the question of whether modern society has been the scene of genuine progress.

It is possible, however, to show that a relativistic moral philosophy is perfectly compatible with a belief in progress, for it is not true that a relativistic philosophy cannot make any meaningful statements about progress because it has to grant that there are different moral standards and that all are equally valid. First, even if there is no way of proving the absolute validity of a moral outlook, there is still a way of intelligently and objectively assessing its credentials. The moral ideals that underlie the indictment of modern civilization for its excessive individualism and egalitarianism made by T. S. Eliot, for example, would require, if they were to be seriously employed as positive programs for action, the dismantling of large segments of industrial society. Since we may assume that those who put forward such criticisms would wish medical science to continue its work, for example, and would accept a world population at something like its present size, we must conclude that their announced preferences are both unrealistic and incoherent because they are incompatible with other values that they also hold. An examination of available resources, of the costs of maintaining or instituting alternative systems of values, and of the utility of these systems as guides to the resolution of definite historical problems provides a way of choosing among competing moral outlooks and makes the choice something more than a matter of personal whim or social convention.

Second, although the philosophical relativist may believe that apart from the specification of definite problems in determinate historical contexts, there is no way of showing that a moral code is valid, this does not mean that he does not himself hold any moral standards or that he is any less attached to them than an absolutist would

be. A twenty-first-century American looking at slavery in ancient Rome, for example, will regard it as a change for the better that slavery is now illegal in Western society, and he will do so whether or not he is a relativist. And to say that he might feel different if he were a Roman is irrelevant, for he is a twenty-first-century American, not a Roman, and it would be a different person with a different identity, not he, who felt different in the hypothetical circumstances. Similarly, if the standards of people in the future change, they may well disagree with us in regard to what has been progressive in history. But if these future judgments reverse present judgments, that does not bind a relativist living here and now to accept them. Nothing in his position requires him to say that progress is any historical trend that comes to be thought desirable.

Progress as a moral standard. As a final consideration, it is important to recognize that the idea of progress in its most important aspect is itself a regulative moral ideal, not simply a belief about history. It represents a directing principle of intellectual and social action, instructing human beings to regard all social arrangements with a critical eye and to reject any claim that any human problem has been finally solved or must be left finally unsolved. To the extent that this idea of progress is embodied in moral codes and social systems, these codes and systems will contain deliberate provision for self-reform. The idea of progress thus represents the social application of the principle that inquiry should be kept open and that no bounds can legitimately be set to the authority of such free inquiry. As such, it would appear to be an indispensable belief for a fully liberal civilization.

PROJECTIVISM

"Projectivism" has its roots in David Hume's remark in the *Treatise* about the mind's "propensity to spread itself

over external objects." We sometimes speak of properties of objects where in fact the features we notice are "projections" of our internal sentiments (or other qualities of our experience). The family of metaethical views claiming that value is a projection of our conative and affective physiological states is called projectivism by Simon Blackburn (1984), and the name has stuck. Blackburn proposes that "we say that [we] *project* an attitude or habit or other commitment which is not descriptive onto the world, when we speak and think as though there were a property of things which our sayings describe, which we can reason about, know about, be wrong about, and so on" (1984, pp. 170–171). In ethics projectivism is popular because it provides an explanation of how it is that moral judgment can have the logical role that it seems to have in deciding what to do. Believing that something has some property typically provides me with a reason to act only in conjunction with the desire to promote (or oppose) the realization of that property. But believing that something is good is (or has been taken historically to be) sufficient by itself to provide a person with a reason to act. Nor is this a coincidence; it is not that we humans happen to like good things, as we happen to like to eat sugary things. Rather, it is part of the logic of judgments of goodness that they provide reasons. How can this be? Projectivists explain: the judgment that something is good is the projection of our affinity toward it, our "appetite," as Thomas Hobbes puts it.

There are three varieties of projectivism to distinguish. The most straightforward is the error theory, advanced by J. L. Mackie (1977, see also Robinson 1948), according to which our projection of value into the world is an illusion. Ordinary moral judgments presuppose an objectivity or independence of moral properties that is simply not to be had, and so they are in error. Mackie sees moral thought and language much as an atheist sees religious talk and language. The believers are not conceptually confused, but they are ontologically mistaken. The second sort of projectivism regards moral properties as Lockean "secondary qualities," not illusions, but real properties that consist in dispositions to affect human perceivers in certain ways. According to John MacDowell (1987), a leading exponent, just as we do not understand what the blueness of an object is except as the disposition to look blue to us, so we do not understand what goodness is except as the disposition to seem good to us. The projection involved in attribution of secondary qualities, including values, involves no error at all.

A third sort of projectivism is noncognitivism, or as it is more commonly called in discussions of projec-

tivism, expressivism. The expressivist holds that moral judgments do not state propositions at all but rather serve to express some noncognitive mental state of the judge. Like secondary-quality theorists, expressivists deny that there is any mistake involved in moral judgment; true, there are no moral properties, and we speak as though there are, but this “speaking as though” is just a misleading feature of the surface grammar. In fact, according to expressivists, moral judgments do not serve the same semantic function as most declarative sentences, even though they look the same.

Blackburn’s projectivist position (the most influential one of the 1980s) develops an expressivist analysis of moral language with enough logical richness and complexity to model real moral deliberation and argument. His idea is easier to make out against the background of common criticisms of expressivism. Richard Brandt (1959), among others, noted that people’s ordinary thinking about moral judgments runs contrary to expressivism. We have generally believed that normative judgments are used to state facts, that they are true or false, and when we change our moral views we come to regard our earlier views as mistaken, not merely as different. (By contrast, when one’s taste in dessert changes, one generally regards the old preference as merely different or, at worst, childish.) Brandt complained that expressivists had given no explanation of why we are so confused. Blackburn’s theory is designed to meet such objections. While maintaining an underlying expressivist semantics, he tries to show why we speak and think as though moral judgments state facts, can be true or false, and so on.

Imagine that people initially spoke about ethics in a language like English but having a quite explicitly expressivist structure. Rather than saying, “Voting for this health-care bill is morally wrong,” they said, “Boo, voting for this health-care bill!” Now imagine that these speakers valued a kind of consistency of sentiment, so that it was regarded as a confusion if someone said, “Boo, eating mammals, and hooray, eating cows!” And suppose they also believed that some moral sensibilities could never survive reflection by a rational person, so that expressing one of those sensibilities would be conclusive evidence that the speaker simply had not thought carefully about the subject. The expressivist community might “invent a predicate answering to that attitude, and treat commitments as if they were judgments, and then use all the natural devices for debating truth” (Blackburn 1984, p. 195). Since Blackburn’s theory seeks to defend realist-style reasoning without realist metaphysics, he calls it “quasi-realism.”

An important objection to Blackburn’s quasi-realism is made by Crispin Wright (1988) and Bob Hale (1990). Our moral language has a realist surface structure, and quasi-realism seeks to vindicate this structure without giving in to realist metaphysics. But if quasi-realism is successful—if every realist-sounding thing we say can be endorsed in good faith by the quasi-realist—then how will a quasi-realist be distinguishable from a full-blooded realist? As Wright puts it, Blackburn’s program confronts a dilemma: Either it does not account for all the realist logical features of moral language, in which case it fails, or it succeeds in accounting for all of them, “in which case it makes good all the things which the projectivist started out wanting to deny: that the discourse in question is genuinely assertoric, aimed at truth, and so on” (1988, p. 35).

Despite these difficulties, projectivism deserves to be taken seriously, not just in the metaphysics of value, but in other metaphysical domains as well. For example, there have been projectivists about mental states (Dennett 1987—judging that someone has intentional states is taking “the intentional stance” toward the person), causes (saying that one event caused another is projecting one’s psychological propensity to associate events of the first kind with events of the second in temporal sequence), probability (Finetti 1972—judgments of probability project one’s degree of credence into the world), and logical impossibility (Blackburn 1984—projecting a certain kind of inconceivability). With the exception of the first, all of these sorts of projectivism are plausibly attributed to Hume, who should be regarded as the prototype projectivist.

James Dreier (1996)

PROMISES

Promising is a device for obligating oneself. In a culture in which promising is available, people have a normative power that they would lack in the absence of this institution. By exercising this power—standardly through the utterance of a linguistic formula—one can bring about changes in the expectations of others in ways that enhance one's ability to pursue their goals and that foster relations of familiarity and trust.

The existence of a normative power of this kind seems philosophically puzzling: How can the utterance of a linguistic formula cause a change in the normative relations that obtain in the world? In response to this question, it might help to situate promising within the general theory of speech acts, noting that it is one of a range of illocutionary acts that may be performed with words (to be set aside such acts as asserting or commanding). In addition, one might point to the conventional aspect of promising, observing that it is a contingent social practice, sustained by interlocking sets of human dispositions, expectations, and sanctions, which enables people to coordinate their behavior in ways that promote the common good. An analogy might be to the institution of contract in the law.

But there is a normative complexity to promises that these remarks fail to capture. Agents who make a promise incur a distinctively moral obligation, opening themselves to corresponding moral complaint if they should

fail to do what they have promised. Moreover this moral dimension seems crucial to the ordinary operation of promises. Promises serve to assure the promisee that something the promisee values will in fact take place—this is one way in which they differ from threats. But they achieve this effect through the promiser's implicit acknowledgement of the moral obligation that is brought into existence by the act of promising itself. Promisers give promisees to understand that they have a distinctively moral reason to do what has been promised, a reason that is strong enough to lead to performance even in the absence of independent reasons for so acting. This in turn grounds the promisee's assurance that the promised performance will take place. What accounts for the moral obligation that thus figures at the center of promissory interactions?

One answer to this question stresses the value to the agent of the normative power involved in promising. The ability to obligate oneself is a great advantage when it comes to pursuing one's projects and developing interpersonal relationships of depth and commitment. One would potentially deprive oneself of this advantageous capacity if one failed to do what one had promised, insofar as people would be less inclined to take one's promissory acts seriously. It may be doubted, however, whether this approach provides a complete account of the moral obligations brought into existence through promising. One issue is the directionality of promissory obligations. The normative powers approach focuses on the moral importance to the promiser of the ability to obligate oneself in this way. But when one fails to do what they have promised, the moral objection to their conduct turns primarily on the effects of their behavior on others.

This dimension of promissory obligations is central to a second approach, the practice view. On this view, the moral wrong involved in promise-breaking derives from the nature of promising as a valuable convention. This basic idea might be developed in a variety of ways, depending on the more general moral theory one favors. Thus, utilitarians invoke the duty to promote the impartial good, arguing that it is a violation of that duty to act in ways that undermine a highly beneficial social practice such as promising. Other theorists appeal to the idea of fairness, contending that it would be unfair to fail to do one's part to sustain a beneficial practice that one has profited from oneself. The moral duty that promising brings into existence is thus traced to fundamental social duties, in accordance with moral principles of utility or fairness.

There are two potential problems with this approach, however. First, it still does not capture the specific directionality of the moral duty involved in promissory acts. On the practice view, everyone who potentially benefits from the useful convention of promising could equally be said to be wronged when a person breaks a promise. Intuitively, however, it appears that the promisee, in particular, has a privileged ground for moral complaint. Second, it would seem possible to wrong another person in precisely the same way without exploiting a social practice such as promising. Thus, even in the absence of a promise A might deliberately lead B to believe that A will do X, where X is something A knows B wants A to do. Under these circumstances, A's failure to do X would appear to wrong B in just the same way a broken promise would have done. Yet this wrong cannot be explained by appeal to more general duties to sustain beneficial practices.

A third approach, the fidelity view, holds that promissory obligations derive from more general duties not to disappoint the expectations one has deliberately raised in others. This approach accounts well for the specific directionality of promissory obligations, and it does so in a way that explains the similarities between breaking a promise and other cases of dashed expectations. But the fidelity view encounters a different problem. It holds that the moral duty to keep one's promise is in place only when the promisee has come to expect that the promiser will perform. But as was seen above, in the promising case this kind of expectation is supposed to derive from the promiser's acknowledgement of the moral obligation to perform. There is thus a potential circularity in the interpretation of promissory interactions that is suggested by the fidelity view.

Much of the philosophical interest of promises derives from their normative complexity. An account that is adequate to this complexity might need to draw on several of the strategies sketched above, in a kind of hybrid approach. For instance, the practice view might explain how the act of promising brings into existence an initial moral obligation that is independent of the promisee's expectations. Perhaps it is the promiser's acknowledgement of this practice-based obligation that generates a corresponding expectation in the promisee. Once such an expectation is in place, the fidelity view could explain why promisers incur a further and specifically directional obligation to perform. Finally, the normative powers approach illuminates the value of the social practice of promising, highlighting the advantages gained from having the ability to obligate oneself through promissory acts.

R. Jay Wallace (2005)

PROOF THEORY

The background to the development of "proof theory" since 1960 is contained in the entry "Mathematics, Foundations of." Briefly, Hilbert's program (HP), inaugurated in the 1920s, aimed to secure the foundations of mathematics by giving finitary consistency proofs of formal systems such as for number theory, analysis, and set theory, in which informal mathematics can be represented directly. These systems are based on classical logic and implicitly or explicitly depend on the assumption of "completed infinite" totalities. Consistency of a system S (containing a modicum of elementary number theory) is sufficient to ensure that any finitarily meaningful statement about the natural numbers that is provable in S is correct under the intended interpretation. Thus, in David Hilbert's view, consistency of S would serve to eliminate the "completed infinite" in favor of the "potential infinite" and thus secure the body of mathematics represented in S. Hilbert established the subject of proof theory as a technical part of mathematical logic by means of which his program was to be carried out; its methods are described below.

In 1931 Kurt Gödel's second incompleteness theorem raised a *prima facie* obstacle to HP for the system Z of elementary number theory (also called Peano arithmetic—PA) since all previously recognized forms of finitary reasoning could be formalized within it. In any case Hilbert's program could not possibly succeed for any system such as set theory in which *all* finitary notions and reasoning could unquestionably be formalized. These obstacles led workers in proof theory to modify HP in two ways. The first was to seek reductions of various formal systems S to more constructive systems S'. The second was to shift the aims from foundational ones to more mathematical ones. Examples of the first modification are the reductions of PA to intuitionistic arithmetic HA and Gentzen's consistency proof of PA by finitary reasoning coupled with quantifier-free transfinite induction up to the ordinal ϵ_0 , $TI(\epsilon_0)$, both obtained in the 1930s. The second modification of proof theory was promoted especially by Georg Kreisel starting in the early 1950s; he showed how constructive mathematical information could be extracted from nonconstructive proofs in number theory. The pursuit of proof theory along the first of these lines has come to be called relativized Hilbert program or reductive proof theory, while that along the second line is sometimes called the program of unwinding proofs or, perhaps better, extractive proof theory. In recent years there have been a number of applications of the latter both in mathematics and in theoretical computer science. Keeping the philosophical relevance and limitations of space in mind, the following account is devoted entirely to developments in reductive proof theory, though the two sides of the subject often go hand in hand.

METHODS OF FINITARY PROOF THEORY

Hilbert introduced a special formalism called the epsilon calculus to carry out his program (the nomenclature is related neither to the ordinal ϵ_0 nor to the membership symbol in set theory), and he proposed a particular substitution method for that calculus. Following Hilbert's suggestions, Wilhelm Ackermann and John von Neumann obtained the first significant results in finitary proof theory in the 1920s. Then, in 1930, another result of the same character for more usual logical formalisms was obtained by Jacques Herbrand, but there were troublesome aspects of his work. In 1934 Gerhard Gentzen introduced new systems, the so-called sequent calculi, to provide a very clear and technically manageable vehicle for proof theory, and reobtained Herbrand's fundamen-

tal theorem via his cut-elimination theorem. Roughly speaking, the latter tells us that every proof of a statement in quantificational logic can be normalized to a direct proof in which there are no detours ("cuts") at any stage via formulas of a complexity higher than what appears at later stages. Sequents have the form $\Gamma \rightarrow \Delta$, where Γ and Δ are finite sequences of formulas (possibly empty). $\Gamma \rightarrow \Delta$ is derivable in Gentzen's calculus LK just in case the formula $A \supset B$ is derivable in one of the usual calculi for classical predicate logic, where A is the conjunction of formulas in Γ and B is the disjunction of those in Δ .

INTRODUCTION OF INFINITARY METHODS TO PROOF THEORY

Gentzen's theorem as it stood could not be used to establish the consistency of PA, where the scheme of induction resists a purely logical treatment, and for this reason he was forced to employ a partial cut-elimination argument whose termination was guaranteed by the principle $TI(\epsilon_0)$. Beginning in the 1950s, Paul Lorenzen and then, much more extensively, Kurt Schütte began to employ certain infinitary extensions of Gentzen's calculi (cf. Schütte, 1960, 1977). This was done first of all for elementary number theory by replacing the usual rule of universal generalization by the so-called ω -rule, in the form: from $\Gamma \rightarrow \Delta, A(n)$ for each $n = 0, 1, 2, \dots$, infer $\Gamma \rightarrow \Delta, (x)A(x)$. Now derivations are well-founded trees (whose tips are the axioms $A \rightarrow A$), and each such is assigned an ordinal as length in a natural way. For this calculus LK_ω , one has a full cut-elimination theorem, and every derivation of a statement in PA can be transformed into a cut-free derivation of the same in LK_ω whose length is less than ϵ_0 . Though infinite, the derivation trees involved are recursive and can be described finitarily, to yield another consistency proof of PA by $TI(\epsilon_0)$. Schütte extended these methods to systems RA_α of ramified analysis (α an ordinal) in which existence of sets is posited at finite and transfinite levels up to α , referring at each stage only to sets introduced at lower levels. Using a suitable extension of LK_ω to RA_ω , Schütte obtained cut-elimination theorems giving natural ordinal bounds for cut-free derivations in terms of the so-called Veblen hierarchy of ordinal functions. In 1963 he and Solomon Feferman independently used this to characterize (in that hierarchy) the ordinal of predicative analysis, defined as the first α for which $TI(\alpha)$ cannot be justified in a system RA_β for $\beta < \alpha$. William Tait (1968) obtained a uniform treatment of arithmetic, ramified analysis, and related unramified systems by means of the cut-elimination theorem for LK extended to a language with formulas built

by countably infinite conjunctions (with the other connectives as usual). Here the appropriate new rule of inference is: from $\Gamma \rightarrow \Delta, A_n$, for each $n = 0, 1, 2, \dots$, infer $\Gamma \rightarrow \Delta, A$, where A is the conjunction of all the A_n 's.

Brief mention should also be made of the extensions of the other methods of proof theory mentioned above, concentrating on elimination of quantifiers rather than cut elimination. In the 1960s Burton Dreben and his students corrected and extended the Herbrand approach (cf. Dreben and Denton, 1970). Tait (1965) made useful conceptual reformulations of Hilbert's substitution method; a number of applications of this method to subsystems of analysis have been obtained in the 1990s by Grigori Mints (1994). Another approach stems from Gödel's functional interpretation, first presented in a lecture in 1941 but not published until 1958 in the journal *Dialectica*; besides the advances with this made by Clifford Spector in 1962, more recently there have been a number of further applications both to subsystems of arithmetic and to subsystems of analysis (cf. Feferman 1993). Finally, mention should be made of the work of Dag Prawitz (1965) on systems of natural deduction, which had also been introduced by Gentzen in 1934 but not further pursued by him; for these a process of normalization takes the place of cut elimination. While each of these other methods has its distinctive merits and advantages, it is the methods of sequent calculi in various finitary and infinitary forms that have received the most widespread use.

PROOF THEORY OF IMPREDICATIVE SYSTEMS

The proof theory of impredicative systems of analysis was initiated by Gaisi Takeuti in the 1960s. He used partial cut-elimination results and established termination by reference to certain well-founded systems of ordinal diagrams (cf. Takeuti 1987). In 1972 William Howard determined the ordinal of a system ID_1 of one arithmetical inductive definition, in the so-called Bachmann hierarchy of ordinal functions; the novel aspect of this was that it makes use of a name for the first uncountable ordinal in order to produce the countable (and in fact recursive) ordinal of ID_1 . In a series of contributions by Harvey Friedman, Tait, Feferman, Wolfram Pohlers, Wilfried Buchholz, and Wilfried Sieg stretching from 1967 into the 1980s, the proof theory of systems of iterated inductive definitions ID_α and related impredicative subsystems of analysis was advanced substantially. The proof-theoretic ordinals of the ID_α were established by Pohlers in terms of higher Bachmann ordinal function systems (cf. Buchholz et al. 1981). The methods here use cut-elimination

arguments for extensions of LK involving formulas built by countably and uncountably long conjunctions. In addition, novel "collapsing" arguments are employed to show how to collapse suitable uncountably long derivations to countable ones in order to obtain the countable (again recursive) ordinal bounds for these systems. An alternative functorial approach to the treatment of iterated inductive definitions was pioneered by Jean-Yves Girard (1985).

In 1982 Gerhard Jäger initiated the use of the so-called admissible fragments of Zermelo-Fraenkel set theory as an illuminating tool in the proof theory of predicatively reducible systems (cf. Jäger 1986). This was extended by Jäger and Pohlers (1982) to yield the proof-theoretical ordinal of a strong impredicative system of analysis; that makes *prima facie* use of the name of the first (recursively) inaccessible ordinal. Michael Rathjen (1994) has gone beyond this to measure the ordinals of much stronger systems of analysis and set theory in terms of systems of recursive ordinal notations involving the names of very large (recursively) inaccessible ordinals, analogous to the so-called large cardinals in set theory.

SIGNIFICANCE OF THE WORK FOR HP AND REDUCTIVE PROOF THEORY

Ironically for the starting point with Hilbert's aims to eliminate the "completed infinite" from the foundations of mathematics, these developments have required the use of highly infinitary concepts and objects to explain the proof-theoretical transformations involved in an understandable way. It is true that in the end these can be explained away in terms of transfinite induction applied to suitable recursive ordinal notation systems. Even so, one finds few who believe that one's confidence in the consistency of the systems of analysis and set theory that have been dealt with so far has been increased as a result of this body of work. However, while the intrinsic significance of the determination of the proof-theoretic ordinals of such systems has not been established, that work can still serve behind the scenes as a tool in reductive proof theory. It is argued in Feferman (1988) that one has obtained thereby foundationally significant reductions, for example of various (*prima facie*) infinitary systems to finitary ones, impredicative to predicative ones, and nonconstructive to constructive ones. With a field that is still evolving at the time of writing, it is premature to try to arrive at more lasting judgments of its permanent value.

PROPER NAMES AND DESCRIPTIONS

A *singular term* is an expression whose semantic function, when used in a particular context, is to *refer to* (denote, designate)—that is, to stand for—a single thing. A *definite description* is a singular noun phrase beginning with the definite article "the" or with a possessive noun or pronoun, as "the author of *Waverley*" and "my brilliant career." Proper names, such as "Shakespeare" and "London," are generally classified along with definite descriptions, individual variables, pronouns, and some other indexicals as singular terms. A French speaker who utters the words "*Londres est jolie*" asserts the same thing as an English speaker uttering "London is pretty." The thing asserted is a *proposition*, that London is pretty. The fundamental semantic role of a declarative sentence is to *express* (or to *contain*) a proposition (*q.v.*), which is the *semantic content* of the sentence. The proposition that Sir Walter Scott is ingenious has some component in common with the proposition that Scott is ingenuous, because both of these are directly about Scott, and some other component again in common with the proposition that Shakespeare is ingenious. These two proposition components are separately correlated with the proper name "Scott" and the predicate "is ingenious." The proposition component semantically correlated with an expression is the expression's *semantic content*. The principal philosophical controversy regarding proper names (and other singular terms) concerns the question: What are their semantic contents? The theories of John Stuart Mill (1806–1873), Bertrand Russell (1872–1970), and Gottlob Frege (1848–1925) provide rival answers.

1. THE NAIVE THEORY AND THE MILLIAN THEORY

One natural theory of semantic content is the naive theory, whose main theses are: (i) the semantic content of any singular term, as used in particular context, is its referent (bearer; the individual referred to); (ii) any semantically contentful expression refers to its semantic content; and (iii) the proposition semantically contained in a sentence is a complex, structured entity whose constituents are the semantic contents of expressions making up the sentence, typically the simple (noncompound) component expressions. (The theory may allow particular sorts of exceptions, as for example those generated by the use of quotation marks.) On the naive theory the proposition contained in “Shakespeare is ingenious” is a *singular proposition*—composed partly of things such as properties, relations, and concepts, and partly of the very individual(s) the proposition is about. By contrast, a (*purely*) *general proposition* is made up exclusively in a certain way of the former sorts of entities. On the naive theory, semantic content and reference collapse into one.

Definite descriptions pose a difficulty for the naive theory because they contain proper parts with semantic content. In *A System of Logic* (1893), Mill proffered a variant of the naive theory on which the proposition contained in “The author of *Waverley* is ingenious” is composed of something involving the attribute of authorship of *Waverley* in place of Scott himself. Mill distinguished between *denotation* (referent) and *connotation*. A general term (“concrete general name”) was said by Mill to “denote” the class of individuals to which the term applies. Mill used the term “connotation” for a semantic content consisting of attributes or properties. General terms were held to have both denotation and connotation. According to Mill, definite descriptions also have both connotation and (typically) denotation, whereas proper names have only denotation. Mill’s theory strongly suggests a systematic modification of the naive theory. The central theses of the Millian theory are: (i) the semantic content of any *simple* (noncompound) singular term is its referent; (ii) any expression refers to its extension; and (iii) the semantic content of a typical contentful compound expression (e.g., a definite description) is a composite entity whose constituents are the semantic contents of expressions making up the compound expression, typically the simple component expressions. (Mill’s actual theory was somewhat more complex, but also somewhat less plausible.)

2. THE PUZZLES

The naive and the Millian theories give rise to philosophical puzzles concerning substitution and nonreferring names. Frege’s puzzle arises from certain sentences, especially identity sentences. The sentence “Hesperus is Phosphorus” (or “The Evening Star is The Morning Star”), by contrast with “Hesperus is Hesperus,” is informative. Its semantic content apparently extends knowledge. It is also a posteriori and synthetic. Yet according to both the naive theory and the Millian theory, the semantic contents of both sentences are composed of the same components, evidently in precisely the same way. Those theories thus ascribe the same semantic content to both sentences. In his early work, *Begriffsschrift* (1972 [1879], §8), Frege proposed solving this puzzle by reading the predicate for numerical identity as covertly metalinguistic: It was held that “Hesperus is Phosphorus” contains a substantive proposition concerning the names “Hesperus” and “Phosphorus,” to the effect that they are co-referential. There are serious difficulties with this account, however, and Frege came to reject it. Most significantly, the account fails to solve the general problem of which “Hesperus is Phosphorus” is a special case. Unless the theory is part of a more sweeping proposal concerning all expressions and not just that of identity predicates, there is no explanation for the analogous difference in epistemic and semantic status between “Hesperus is a planet if Phosphorus is” (synthetic *a posteriori*) and “Hesperus is a planet if Hesperus is” (analytic *a priori*).

A second puzzle is the apparent failure of substitution in special contexts, especially those of propositional attitude. Jones may sincerely and reflectively assent to “Hesperus appears in the evening sky” and sincerely and reflectively dissent from “Phosphorus appears in the evening sky,” even while fully grasping their semantic content. This appears to violate the classical logical rule of Leibniz’s law, or the substitutivity of equality. Both the naive theory and the Millian theory treat “Jones believes that Hesperus appears in the evening” and its substitution instance “Jones believes that Phosphorus appears in the evening” as having the same content, and therefore also the same truth-value.

A further nest of problems concerns sentences involving nonreferring proper names. The sentence “Sherlock Holmes is addicted to cocaine” clearly has content. Yet on both the naive theory and the Millian theory, the semantic content of any sentence will lack a necessary component if any contained name lacks a referent. It is evident, moreover, that this sentence (taken as a statement of real fact, rather than as a statement made from

within the fiction) cannot be counted literally true. But, it seems, neither can its negation—“Sherlock Holmes is not addicted to cocaine”—be truly uttered. This seems to violate the classical law of excluded middle. These puzzles are especially pressing with regard to negative existentials, such as “Sherlock Holmes does not exist.” This sentence is true if and only if “Sherlock Holmes exists” is false, and therefore, it would seem, if and only if the referent of “Sherlock Holmes” lacks existence. Yet the negative existential itself implies that the name does not so much as have a referent. How, then, can it be true? Indeed, how can it have any content at all?

3. RUSSELL’S THEORY OF DESCRIPTIONS

Russell’s semantic theory (post-1904) is a supplement to the naive theory. Russell employed *propositional functions* in lieu of attributes. A propositional function assigns to any objects in its domain a singular proposition concerning those objects. Russell’s general theory of descriptions, or of what he called “denoting phrases,” consisting of a noun phrase preceded by a determiner such as “all” or “some,” assigns a content to sentences in which they figure while denying that the determiner phrases themselves are meaningful units. The theory analyzes sentences of both the Aristotelian *A* form, “ $\Pi(\text{all } S)$ ” (e.g., “All millionaires are wealthy”), and the *I* form, “ $\Pi(\text{some } S)$,” where Π is a monadic predicate. (More generally, Π may be the result of filling all but one of the argument positions of an n -adic predicate, $n \geq 1$.) The *A* form is analyzed as “For everything x , if x is a S , then $\Pi(x)$ ”—more colloquially as, “Everything is such that: if it is a S , then $\Pi(\text{it})$ ” (“Everything is, if a millionaire, then wealthy”). The complex predicate “is such that: if it is a S , then $\Pi(\text{it})$ ” stands for a certain propositional function, whereas the quantifier “everything” stands for a higher-level propositional function, which assigns to any first-level propositional function, F , the proposition that F is “always true”—that is, the proposition that F yields a true proposition for each and every argument.

Russell analyzed “ $\Pi(\text{some } S)$ ” as “Something is such that: it is a S and $\Pi(\text{it})$ ”—wherein the complex predicate “is such that: it is a S and $\Pi(\text{it})$ ” stands for a certain propositional function said to be “sometimes true”—that is, to yield a true proposition for at least one argument. An English phrase of the form “all S ” thus corresponds to the incomplete string, “everything is such that: if it is a S , then it ...,” and a phrase of the form “some S ” corresponds to the incomplete string, “something is such that: it is a S and it....” Russell called phrases of either form

incomplete symbols. The sentences in which such phrases figure have content, though the phrase, in and of itself, does not contribute a proposition-component to the proposition expressed. As Russell put it in “On Denoting,” “denoting phrases have no meaning in isolation.”

The introduction of a quantifier (“everything,” “something”) into the analysis gives rise to ambiguities analogous to that of “every boy kissed a girl” when the simple Aristotelian sentential form occurs within the scope of a governing operator, such as “not,” “necessarily,” or “Jones believes.” Thus, on Russell’s general theory of descriptions, a sentence of the form “not $\Pi(\text{all } S)$ ” (e.g., “All millionaires are not wealthy”) may be analyzed by giving the indefinite description “all S ” *primary occurrence* (over “not”), yielding: “Everything is such that: if it is a S , then not- $\Pi(\text{it})$.” This reading is equivalent to the Aristotelian *E* form, “ $\Pi(\text{no } S)$.” Alternatively, and nonequivalently, “not $\Pi(\text{all } S)$ ” may be analyzed by giving the phrase “all S ” *secondary occurrence*, yielding the reading, “Not everything is such that: if it is a S , then $\Pi(\text{it})$.” (The latter analysis—equivalent to the Aristotelian *E* form—is obtained by letting the negation in “not $\Pi(\text{all } S)$ ” govern the entire *A* form, not just its predicate Π .) Similarly, “Jones believes $\Pi(\text{some } S)$ ” may be analyzed as “Something is such that: it is S and Jones believes that $\Pi(\text{it})$ ” (primary occurrence), or alternatively, and nonequivalently, as “Jones believes: that $\Pi(\text{some } S)$ ” (secondary).

In most cases, only one of the two readings is plausibly intended (as with “Jones believes some husbands are bachelors”). If the simple Aristotelian *A* or *I* form occurs with two or more governing operators, the number of readings is compounded. For example, “Jones believes some millionaires are not wealthy” may be analyzed alternatively, and nonequivalently, as: (i) “Someone is a millionaire and Jones believes he/she is not wealthy” (*wide scope*); (ii) “Jones believes: that someone is both a millionaire and not wealthy” (*intermediate scope*); or (iii) “Jones believes: that no one is both a millionaire and wealthy” (*narrow scope*).

The central tenet of Russell’s theory of definite descriptions is that a description such as “the author of *Waverley*” (used in the sense of “the sole author of *Waverley*”) is semantically equivalent to the corresponding uniqueness-restricted existential quantifier “some unique author of *Waverley*,” in the sense of “something such that it, and nothing else, wrote *Waverley*.” The restricted quantifier falls under the purview of Russell’s general theory of descriptions. On Russell’s theory, then, “the author of *Waverley*” corresponds to the string “Someone is such that: he or she uniquely wrote *Waverley* and he or

she ... ,” making definite descriptions also “incomplete symbols” which have “no meaning in isolation.” The words “The author of *Waverley* is ingenious” are not directly about Walter Scott, but about the complex propositional function, *being a unique author of Waverley who is also ingenious*, expressing that this function yields a true proposition for at least one individual. There is nothing that the phrase “the author of *Waverley*” contributes on its own to this proposition.

As with “some S,” sentences that position a definite description within governing operators yield multiple readings. For example, “Jones believes the author of *Waverley* is not ingenious” may be analyzed alternatively, and nonequivalently, as: (i) “Someone uniquely wrote *Waverley* and Jones believes he is not ingenious”—that is, Jones believes of *Waverley*’s sole author that *he* is not ingenious (*wide scope*); (ii) “Jones believes: that someone both uniquely wrote *Waverley* and is not ingenious”—that is, Jones believes that whoever wrote *Waverley* single-handedly is not ingenious (*intermediate scope*); or (iii) “Jones believes: that no one both uniquely wrote *Waverley* and is ingenious” (*narrow scope*). The wide-scope reading is consistent with Jones’s belief not involving a conception of Scott as sole author of *Waverley*. The narrow-scope reading attributes a belief that is consistent with *Waverley* not having a sole author.

A definite description is said to be *proper* when there is someone or something that uniquely answers to the description, and is *improper* otherwise. Russell artificially, and misleadingly, extended Mill’s term “denotation” to the semantic relation that obtains between a proper definite description and the individual uniquely described, even though a definite description is supposed not to be a singular term. He might instead have called this relation “simulated denotation.” Russell retained the term “meaning” for semantic content.

Both the Millian theory and Russell’s theory deny that the individual that uniquely answers to a definite description is itself a component of the content of sentences involving the description. Those theories are able to solve the puzzles in the special case where the terms involved are definite descriptions rather than proper names, by reading sentences involving definite descriptions as containing propositions involving corresponding attributes or propositional functions. In particular, Russell’s claim that definite descriptions are not singular terms, but quantificational constructions, blocks substitutivity of equality, which is applicable only to singular terms, from licensing the substitution of “the first Postmaster General” for “the inventor of bifocals” in the

secondary-occurrence reading of “Jones believes that the inventor of bifocals was clever.” (By contrast, the envisioned substitution is indeed licensed by logical principles, including substitutivity as applied to variables, when the sentence takes on its primary-occurrence reading.)

Russell handled the same difficulties in the case of proper names (and such devices as demonstratives) through his thesis that names are ordinarily not used as “genuine names” (singular terms). Instead they were held to be “disguised” or “abbreviated” definite descriptions. The proposition expressed by a sentence involving a typical name is to be analyzed in accordance with Russell’s theory of descriptions. This blocks substitution in sentences such as “Jones believes that Hesperus appears in the evening.” Russell acknowledged the possibility of “names in the strict, logical sense” (logically proper names), which function in accordance with the naive theory. The class of admissible semantic contents for usable genuine names was severely limited by Russell’s principle of acquaintance, that every proposition one can grasp must be composed entirely of constituents with respect to which one has a special sort of intimate and direct epistemic access, (*direct acquaintance*). This restriction seems sufficient to prevent the puzzles from arising with logically proper names. (Russell did not countenance genuine names lacking a referent. Curiously, he claimed that singular existential and negative existential statements involving genuine names are without meaning. It would have been better to say that such sentences are always trivially true and trivially false, respectively.)

4. FREGE’S THEORY OF SINN AND BEDEUTUNG

In his classic paper, “*Über Sinn und Bedeutung*” (1892), Frege abandoned the naive theory in favor of a richly elegant philosophy of semantics, which extends the Millian theory’s two-tiered semantics for definite descriptions and predicates to include all meaningful expressions. (Like Mill, and unlike Russell, Frege counted definite descriptions as singular terms.) Frege distinguished between the referent (*Bedeutung*) of an expression and its sense (*Sinn*). The sense of an expression contains a purely conceptual manner of presenting the name’s referent. Individuals that are not themselves senses—such as persons and even their sensations—cannot be constituents of a genuine Fregean sense. Furthermore, the sense of a singular term secures the term’s referent. An expression’s sense is a conception of something, and the expression’s referent, if there is one, is whatever uniquely fits the concept. The reference relation is thus the relative product of

a purely semantic relation (that between an expression and its sense) and a nonlinguistic relation (that between a sense and the object that fits it). Third, the sense of an expression is the semantic content. Expressions having the same sense must have the same referent, but importantly, expressions having the same referent may differ in sense. Frege illustrated his notion of sense by means of three lines that intersect in a single point. Then the phrases “the point of intersection of *a* and *b*,” “the point of intersection of *a* and *c*,” and “the point of intersection of *b* and *c*” converge in reference but diverge in sense.

The observation that proper names have a sense, as distinct from the referent, is tailor-made to solve both Frege’s Puzzle and the problem of how sentences involving nonreferring names can have content. Frege’s solution to the substitution problem is more complex. Crucial to Frege’s theory are the principles of extensionality and compositionality. They hold that the referent or sense, respectively, of a complex expression is a function of the referents or senses, respectively, of the component expressions. In the latter case Frege spoke metaphorically of the sense of a constituent expression as a *part* of the sense of the complex expression, so that the sense of the whole is composed of the senses of the parts.

Thus, if a constituent expression is replaced by one having the same sense, the sense of the whole is preserved, whereas if a constituent expression is replaced by one having the same referent but a different sense, the referent of the whole is preserved even though the sense is not. In particular, Frege held as a special case of extensionality that a compound expression having a nonreferring part must be nonreferring (“Sherlock Holmes’s older brother”). Frege argued, using extensionality, that the *cognitive value* (*Erkenntniswerte*) of a sentence is not the referent of the sentence, but is fixed by its sense, and that the referent of a sentence is one of two truth values, truth and falsity (“the true” and “the false”). Because a sentence refers to its truth-value, and a sentence involving a nonreferring name itself refers to nothing, such a sentence as “Sherlock Holmes is addicted to cocaine” is neither true nor false. (Frege held that the sentence *presupposes*, without asserting, that Sherlock Holmes exists.)

Frege argued that certain expressions create a special context in which subordinate expressions do not refer to their customary referent. When occurring within quotation marks (for example, in “direct discourse” reporting the words used by a speaker) an expression refers to itself. Analogously, expressions occurring subordinate to operators such as “Jones believes that” and “Jones said that” (the latter occurring in “indirect discourse” reporting the

content of a speaker’s utterance) refer to their *ungerade* (indirect, oblique) referent, which is the customary sense. Extensionality is to be understood as requiring the validity of substituting for a name in a sentence any expression having the same referent *in that same position*. (Scattered remarks suggest that Frege might have applied his doctrine of semantic shifting also to the problem of negative existentials.)

5. THE THEORY OF DIRECT REFERENCE

Despite a fundamental disagreement over the matter of singular propositions, there is common ground between Russell and Frege in regard to ordinary proper names. Both held a strong version of the theory that names are *descriptive*. On their view, if “St. Anne” is analyzable as “the mother of Mary,” it must be analyzable even further, because “Mary” is also supposed to be descriptive. But even “the mother of the mother of Jesus” must be in this sense further analyzable. If “ α ” is a nondescriptive singular term referring to Mary, then it may be said that the description “the mother of α ” is *descriptive relative to Mary*. A *thoroughly descriptive* term is one that is descriptive but not descriptive relative to anything. The orthodox theory, shared by Russell and Frege, is the theory that proper names and similar devices are either thoroughly descriptive or descriptive relative only to items of direct acquaintance. Frege held the stronger thesis (which is retained by contemporary variants of Frege’s theory, such as that of John Searle) that proper names are thoroughly descriptive. Any departure from the stronger thesis would constitute a rejection of fundamental Fregean theory.

In recent philosophy the orthodox theory has been forcefully challenged, most notably by Keith Donnellan (1972), David Kaplan, Saul Kripke (1972, 1979), Ruth Barcan Marcus, and Hilary Putnam. These philosophers favor the theory of direct reference, which holds that proper names (and similar devices) are nondescriptive. Importantly, this theory does not deny that particular names may exhibit any or all of the three aspects of a Fregean sense mentioned in the previous section. What is denied is that the conceptual representation carried by a name secures the referent. But the direct-reference theory is significantly stronger than a simple denial of Russell’s doctrine that ordinary names are abbreviated definite descriptions. The theory holds that names are not even similar to definite descriptions. An immediate consequence is that a great many definite descriptions fail to be thoroughly descriptive or descriptive relative only to

items of direct acquaintance, because many contain names of ordinary individuals.

Three main kinds of arguments have been advanced in favor of the direct-reference theory. The modal and epistemological arguments are due chiefly to Kripke. Suppose for simplicity that the name “Shakespeare” simply means “the English playwright who wrote *Hamlet*, *Macbeth*, and *Romeo and Juliet*.” If the orthodox theory of names is correct, then the sentence, “Someone is Shakespeare iff he is an English playwright who is sole author of *Hamlet*, *Macbeth*, and *Romeo and Juliet*,” should express a necessary, a priori truth. On the contrary, however, it might have come to pass that Shakespeare elected to enter a profession in law instead of becoming a writer. Furthermore, it is possible, and is not ruled out solely by semantic reflection, that Francis Bacon should go on to write these plays. These intuitions are supported by a complementary intuition: that “Shakespeare” continues to refer to the same person even with respect to nonactual possible worlds in which Shakespeare lacks the distinguishing characteristics that people actually use to identify him—that is, even in discourse about such a counterfactual scenario. One important consequence of the direct-reference theory is that any proper name is a *rigid designator* (Kripke)—that is, it designates the same thing with respect to every possible world in which that thing exists and does not designate anything else with respect to other possible worlds.

One example of the semantic arguments for the direct-reference theory comes from Donnellan: According to the orthodox theory, the semantic content of the name “Thales” is determined by a description such as “the Greek philosopher who held that all is water.” But suppose that the man referred to by writers from whom the use of the name “Thales” derives never genuinely believed that all is water but was thought to, owing to some error or hoax, and that, by coincidence, there was a Greek hermit who did hold this bizarre view, though he bears no historical connection to anyone. Contrary to the orthodox theory, the name “Thales” would nevertheless refer to the first of the two. This argument seems to reveal also that the surrounding settings in which speakers find themselves, and not merely the concepts evoked in them, are crucial to determining the referents of the names they use. In a word, the securing of a referent for a name is a *contextual* phenomenon. Donnellan and Kripke have provided partial accounts of the securing of a referent for a name by means of historical chains of communication. Putnam has given a similar account of certain terms designating something by means of a “division of linguistic

labor.” Because of these accounts the direct-reference theory is sometimes called the causal theory of reference.

6. THE MILLIAN THEORY RECONSIDERED

What, then, is the semantic content of a name? It is tempting to answer that it is, or at least includes, a descriptive or conceptual “mode of presentation.” Although this proposal does not require that the associated mode of presentation secure the referent, it faces some of the same difficulties as the orthodox theory. A more general difficulty arises because the variations of the argument from Frege’s Puzzle against the naive theory and the Millian theory can be mounted against a wide variety of theories of semantic content, including Frege’s. The general strategy involved in that argument, however, seems to involve an error. This might be demonstrated through an application to a situation involving expressions for which it is uncontroversial that semantic content is exactly the same.

Suppose that foreign-born Sasha learns the words “ketchup” and “catsup” by actually consuming the condiment and reading the labels on the bottles. Suppose further that, because of his idiosyncratic experience, Sasha comes to believe that the substances so named are different condiments sharing a similar taste, color, and consistency. Whereas “Ketchup is ketchup” is uninformative for Sasha, “Catsup is ketchup” is informative. It would be a mistake, however, to conclude that “catsup” and “ketchup” differ in semantic content for Sasha. The terms are perfectly synonymous in English; indeed, they are arguably the same English word. Most English speakers learned one in a sort of ostensive definition, and the other as a strict synonym (or as an alternative spelling) of the first. If either may be learned by ostensive definition, then both may be—witness Sasha. This discredits the original argument from Frege’s puzzle.

One important consideration favoring the Millian theory over the orthodox theory comes by consideration of individual variables. Consider the following propositional-attitude attribution:

- (1) The planet Venus is an individual x such that Jones believes that x is a star.

It is characteristic of this *de re* (as opposed to *de dicto*) locution that it does not specify how Jones is supposed to conceive of Venus in believing it to be a star. The Orthodox Theorist contends that this is a result of the allegedly descriptive name “Venus” positioned outside of the scope of the nonextensional operator “Jones believes

that,” where it is open to substitution and to existential generalization. What is more significant, however, is that a nondescriptive singular term is positioned within the scope of the nonextensional context: the last occurrence of the variable “*x*” in (1). It follows by the principles of conventional semantics that (1) is true if and only if its component open sentence:

(2) Jones believes that *x* is a star

is true under the assignment of Venus as value for the variable. In turn, (2) is true under this assignment if and only if Jones believes the semantic content of the complete open sentence:

(3) *x* is a star

under the same assignment. But the fundamental characteristic of a variable with an assigned referent is that its semantic content is just its referent. This is precisely the point of using a variable rather than a definite description (such as “the first heavenly body visible at dusk”) within the scope of an attitude verb in a *de re* attribution. If a variable with an assigned value had, in addition to its value, a Fregean sense, then (3) would contain a specific general proposition, under the relevant assignment. If (1) is to fail to specify how Jones conceives of Venus, the content of (3) under the assignment of Venus to “*x*” can only be the singular proposition about Venus that it is a star. If the open sentence (3), under the assignment of Venus as the value of “*x*,” contains the singular proposition about Venus that it is a star, then so does the closed sentence “*a* is a star,” where “*a*” is an individual constant that refers to Venus. It is not the variability of a variable, but its structural simplicity, that gives it the feature that the variable’s semantic content, under an assignment of a referent, is just the assigned referent. (An exactly parallel argument proceeds using pronouns in place of variables, using “The planet Venus is such that Jones believes that *it* is a star.”)

It is important to note also that at least some aspects of the remaining puzzles would arise even in a language for which it was stipulated that the Millian theory is correct. Suppose, for example, that an authoritative linguistic committee that legislates the grammar and semantics of the language, and to which all speakers of the language give their cooperation and consent, decreed that proper names are to function exactly like the mathematician’s variables, “*x*,” “*y*,” and “*z*,” except that they are to remain constant. Ordinary speakers would presumably continue to regard co-referential names as not always interchangeable in propositional-attitude attributions. English speakers who use “ketchup” and “catsup” as exact synonyms may be inclined to assent to “Sasha believes that

ketchup is a sandwich condiment, but he does not believe that catsup is.” On philosophical reflection, however, it emerges that this expresses a logical impossibility. Similarly, speakers who agree to abide by the legislative committee’s decree about proper names might for independent pragmatic reasons be led to utter or to assent to such sentences as “Jones believes that Hesperus appears in the evening, but he does not believe that Phosphorus does.” Insofar as the same phenomena that give rise to the puzzles would arise even in the case of a language for which the Millian theory was true by fiat and unanimous consent (and do in fact arise with respect to such straightforward synonyms as “ketchup” and “catsup”), the puzzles cannot be taken as evidence against the Millian theory. A deeper understanding is needed of the puzzles, and a reexamination of the Millian theory in light of this deeper understanding.

Nathan Salmon (2005)

PROPERTIES

Our every assertion or thought involves "properties" or relations. Most simply, we predicate some property of some thing: Earth is round. Sometimes we refer to properties by name or by description: Red is the color of blood. Sometimes our quantifiers range over properties: Galaxies come in many shapes and sizes.

This familiarity with properties, however, does not reveal what properties are. Indeed, the question is equivocal, both in ordinary and in philosophical discourse. There are different conceptions of properties, equally legitimate, corresponding to the different roles that properties have been called upon to play (Bealer 1982; Lewis 1983, 1986). And for each conception there are different theories as to what sort of entity, if any, is best suited to play the role. The most fundamental division is between abundant and sparse conceptions of properties. On an abundant conception every meaningful predicate expresses some property or relation, including "is blue or round," "is on top of a turtle," "is identical with the planet Mars"; a property's instances need not resemble one another in any intrinsic respect. Abundant properties are needed to serve as "meanings," or components of "meanings," in a compositional semantics for language. On a sparse conception of properties a predicate expresses a property only if the objects satisfying the predicate resemble one another in some specific intrinsic respect; perhaps "has unit positive charge" and "is ten kilograms

in mass" are examples. Sparse properties are needed to provide an objective basis for the scientist's project of discovering the fundamental classifications of things and the laws that govern them. Properties, whether abundantly or sparsely conceived, are neither language- nor mind-dependent: They existed before there were beings to talk and think about them; they would have existed even had there never been such beings.

In this entry only conceptions of properties are explicitly distinguished and discussed, although much of what is said applies also to relations and to propositions. Other philosophers' terms for *property* in the abundant sense include *attribute* (Quine 1970), *propositional function* (Russell 1919), and *concept* (Bealer 1982, Frege 1884); *universal* and *quality* have for the most part been interpreted sparsely. Ordinary language allows abundant or sparse readings of *characteristic*, *feature*, *trait*, and more.

ABUNDANT CONCEPTIONS OF PROPERTIES

How abundant are the properties on the abundant conception? Whenever there are some things, no matter how scattered or dissimilar from one another, there is the abundant property of being one of those things. Thus, for any class of things, there is at least one abundant property had by all and only the members of that class. It follows that there are at least as many abundant properties as classes of things and that the abundant properties outrun the predicates of any ordinary language. (There are non-denumerably many classes of things—assuming an infinity of things—but at most denumerably many predicates in any ordinary language.) Abundant properties, owing to their very abundance, must be transcendent, rather than immanent: They are not present in their instances as constituents or parts. It is not plausible to suppose that an object has a distinct constituent for each and every class to which it belongs.

If we say that whenever there are some things, there is exactly one property had by all and only those things, then a property may be identified with the class of its instances. For example, the property of being human may be identified with the class of human beings. But there is a well-known objection to this identification (Quine 1970). Consider the property expressed by "is a creature with a heart" and the property expressed by "is a creature with kidneys." If properties are "meanings," or semantic values, of predicates, then the properties expressed by these two predicates are distinct. Yet, these predicates, we may suppose, are coextensive: As a matter of fact, any creature with a heart has kidneys, and vice versa; the class

of creatures with a heart is identical with the class of creatures with kidneys. Thus, distinct properties correspond to the same class and cannot be identified with that class.

Different responses to the objection invoke different criteria of individuation for properties, that is, different criteria for deciding when properties, introduced, say, via predicates that express them, are one and the same. One response simply denies that “is a creature with a heart” and “is a creature with kidneys” express distinct properties. More generally, properties expressed by coextensive predicates are identical. Call this an extensional conception of properties. A property so conceived may be identified with the class of its instances. Extensional conceptions of properties are adequate to the semantic analysis of mathematical language and extensional languages generally (Tarski 1946).

A second response holds that “is a creature with a heart” and “is a creature with kidneys” express distinct properties, because it is logically possible for something to satisfy one predicate without satisfying the other. On this response properties expressed by necessarily coextensive predicates are identical; properties expressed by accidentally coextensive predicates are distinct. Call this an intensional conception of properties. If one accepts the standard analyses of logical possibility and necessity in terms of *possibilia*, then a property, on the intensional conception, may be identified with the function that assigns to each possible world the set of possible objects that has the property at the world. If one holds that each object exists at, and has properties at, only one world, then a property may more simply be identified with the class of (actual and) possible objects that has the property (Lewis 1986). Properties, on the intensional conception, are appropriate semantic values for predicates of (standard) modal languages and intensional languages generally (Carnap 1947, Kripke 1963).

A third response holds that the properties expressed by “is a creature with a heart” and “is a creature with kidneys” are distinct because they are structured entities with different constituents: The property expressed by “is a creature with a heart” has the property expressed by “is a heart” as a constituent; the property expressed by “is a creature with kidneys” does not. On this response properties have a quasi-syntactic structure that parallels the structure of predicates that express them. Call two predicates isomorphic if they have the same syntactic structure and corresponding syntactic components are assigned the same semantic values. On a structured conception of properties, properties expressed by isomorphic predicates are identical; properties expressed by nonisomorphic

predicates are distinct. (Structured conceptions are sometimes called hyperintensional because they allow necessarily coextensive predicates to express distinct properties.) Structured conceptions subdivide according to whether the unstructured semantic values are intensional or extensional and according to whether the relevant structure is surface grammatical structure, or some hypothetical deep structure, or structure after analysis in terms of some chosen primitive vocabulary. Structured properties may be identified with sequences of unstructured properties and other unstructured semantic values. Structured properties, on one version or another, have a role to play in the semantic analysis of propositional attitudes and of hyperintensional languages generally (Carnap 1947, Cresswell 1985).

Thus far, this entry has assumed that predicates of ordinary language are satisfied by objects once and for all. In fact, most ordinary language predicates are tensed; they may be satisfied by objects at some times but not at others. For example, “is sitting” is true of me now, but was false of me ten minutes ago. On a tensed conception of properties, whether or not a property holds of an object may also be relative to times. Most simply, tensed properties may be identified with functions from times to untensed properties. Tensed properties may be taken as semantic values for tensed predicates.

We have, then, a plurality of abundant conceptions of properties. Which is correct? One need not and should not choose. A plurality of conceptions is needed to account for the multiple ambiguity in our ordinary talk of properties. And it seems that both structured and intensional conceptions are needed for compositional semantics: Structured properties are needed to provide distinct semantic values for predicates, such as “is a polygon with three sides” and “is a polygon with three angles,” that are necessarily coextensive without being synonymous; intensional properties are needed to provide distinct semantic values for unstructured predicates that are accidentally coextensive. To accept a plurality of conceptions, it suffices to find, for each conception, entities that satisfy that conception’s criteria of individuation.

Realists with respect to some conception of properties hold that entities satisfying the individuation criteria for the conception exist. Realists divide into reductionists and antireductionists. Reductionists identify properties, under the various conceptions, with various set-theoretic constructions (in ways already noted): class, functions, or sequences of actual or possible objects (Lewis 1986). Antireductionists reject some or all of these identifications. For some antireductionists, classes are suspect or

esoteric entities; classes are to be explained, if at all, in terms of properties, not vice versa (Bealer 1982, Russell 1919). For other antireductionists the problem is not with classes, but with the possibilia that comprise them (on intensional conceptions). Possible but nonactual entities are to be explained, if at all, in terms of uninstantiated properties, not vice versa (Plantinga 1976). According to the antireductionist, properties are basic or primitive; it is merely posited that there are entities satisfying the appropriate individuation criteria. Some entities, after all, must be taken as basic; according to the antireductionist, properties are an acceptable choice.

Eliminativists hold that, strictly speaking, there are no properties. They take aim, typically, at intensional conceptions, at conceptions with modal criteria of individuation. They claim that modal notions, such as logical possibility and necessity (whether taken as primitive or analyzed in terms of possibilia), incorrigibly lack the clarity and precision required of a rigorous scientific semantics or philosophy (Quine 1970). Eliminativists have the burden of showing how ordinary and philosophical discourse ostensibly referring to properties can be paraphrased so as to avoid such reference; or, failing that, of showing that such discourse is dispensable, merely a *façon de parler*.

SPARSE CONCEPTIONS OF PROPERTIES

On an abundant conception any two objects share infinitely many properties and fail to share infinitely many others, whether the objects are utterly dissimilar or exact duplicates. On a sparse conception the sharing of properties always makes for genuine similarity; exact duplicates have all of their properties in common. Whatever the sparse properties turn out to be, there must be enough of them (together with sparse relations) to provide the basis for a complete qualitative description of the world, including its laws and causal features. The sparse properties correspond one-to-one with a select minority of the abundant properties, on some intensional conception. (“Intensional,” because distinct sparse properties may accidentally be instantiated by the same objects.) Those abundant properties that correspond to sparse properties are called natural (or perfectly natural, since naturalness presumably comes in degrees; Lewis 1983, 1986). The naturalness of properties is determined not by our psychological makeup, or our conventions, but by nature itself.

How sparse are the properties, on a sparse conception? First, there is the question of uninstantiated properties. If sparse properties are transcendent, there is no

difficulty making room for uninstantiated sparse properties; perhaps uninstantiated sparse properties are needed to ground laws that come into play only if certain contingent conditions are satisfied (Tooley 1987). If, on the other hand, sparse properties are immanent, are present in their instances, then uninstantiated sparse properties must be rejected, because they have nowhere to be (Armstrong 1978, 1989). Of course, uninstantiated sparse properties may nonetheless possibly exist, where this is understood according to one’s favored interpretation of modality.

Second, there is the question of the compounding of sparse properties (and relations). Disjunctions and negations of natural properties are not themselves natural: Their instances need not resemble one another in any intrinsic respect. For example, instances of the property having-unit-positive-charge-or-being-ten-kilograms-in-mass need not resemble one another in either their charge or their mass. It follows that there are no disjunctive or negative sparse properties (Armstrong 1978).

The case of conjunctive sparse properties is less clear. There are two views. According to the first, since instances of a conjunction of natural properties, such as having-unit-positive-charge-and-being-ten-kilograms-in-mass, resemble one another in some—indeed, at least two—intrinsic respects, there exists a sparse property corresponding to the conjunction. According to the second view, the sparse properties must be nonredundant; they must be not only sufficient for describing the world but minimally sufficient. On this view conjunctive sparse properties are excluded on grounds of redundancy: A putative conjunctive sparse property would hold of an object just in case both conjuncts hold.

Similarly, structural sparse properties, such as being-a-molecule-of-H₂O, may be admitted on the grounds that they make for similarity among their instances. Or they may be excluded on grounds of redundancy: A putative structural sparse property would hold of an object just in case certain other sparse properties and relations hold among the object and its parts. But the exclusion of structural (and conjunctive) sparse properties faces a problem. It rules out a priori the possibility that some properties are irresolvably infinitely complex: They are structures of structures of structures, and so on, without ever reaching simple, fundamental properties or relations (Armstrong 1978). A sparse conception that allowed for this possibility would have to allow some redundancy; and if some redundancy, why not more? This suggests that conjunctive and structural sparse properties should generally be admitted. (An alternative treatment makes use of degrees

of naturalness and has it that conjunctive and structural properties are natural to some lesser degree than the properties in terms of which they are defined; a world with endless structure has no perfectly natural properties.)

If structural sparse properties are admitted, the sparse properties will not be confined to fundamental physical properties; there will be sparse properties of macroscopic, as well as microscopic, objects. For example, the sparse properties will include specific shape-and-size properties, such as being-a-sphere-ten-meters-in-diameter (which are arguably structural properties definable in terms of sparse distance relations). However, the vast majority of ordinary-language predicates—“is red,” “is human,” “is a chair,” to name a few—fail to express natural properties to which sparse properties correspond; rather, these predicates express properties that, when analyzed in fundamental physical terms, are disjunctive (perhaps infinitely so) and probably extrinsic. (This judgment could be overturned, however, if there are irreducible natural properties applying to macroscopic objects—most notably, irreducible phenomenological properties of color, sound, and such.)

What are the properties on a sparse conception? There are three principal theories (or clusters of theories, since they each subdivide). According to the first, the properties sparsely conceived are just some of the properties abundantly conceived: The properties that are perfectly natural. What makes some properties natural and others unnatural? One version of the theory simply takes naturalness to be a primitive, unanalyzable distinction among abundant properties (Quinton 1957; see also Armstrong 1989, Lewis 1986). But since a property is natural in virtue of the resemblances among its instances, it might seem more appropriate to take instead some relation of partial resemblance as primitive and to define naturalness in terms of resemblance. The resulting version, called resemblance nominalism, can be worked out in different ways with different primitive resemblance relation (Price 1953; see also Armstrong 1989, Goodman 1951; Lewis 1983). The chief objection to the view is that partial resemblance between ordinary objects, no less than naturalness of properties, cries out for analysis. When two objects partially resemble one another, the objection goes, they must have constituents that exactly resemble one another, perhaps constituents that are literally identical. More generally, it is argued, properties must be constituents of objects if properties are to play a role in the explanation of the natures and causal powers of objects; one cannot explain an object’s nature or causal powers by

invoking a class to which it belongs. Sparse properties, then, must be immanent, not transcendent, entities.

What are these constituents of ordinary things? Not ordinary spatial or temporal constituents—or, at least, not always. For even an object with no spatial or temporal extension might have a complex nature and stand in relations of partial resemblance. If sparse properties are immanent, then they must be nonspatiotemporal constituents of things. There are two prominent theories as to the nature of these constituents. The first theory takes them to be universals (Armstrong 1978, 1989.) They are repeatable: Each of them is, or could be, multiply instantiated. And they are wholly present in their instances: An immanent universal is located—all of it—wherever each of its instances is located. When objects resemble one another by having a sparse property in common, there is something literally identical between the objects. It follows that universals fail to obey commonsense principles of location, such as that nothing can be (wholly) in two places at the same time. But that is no objection. Such principles were framed with particulars in mind; it would beg the question against universals to require them to meet standards set for particulars.

On the other theory of sparse properties as immanent, the nonspatiotemporal constituents of ordinary particulars are themselves particulars, called tropes (Armstrong 1989, Lewis 1986, Williams 1966) or abstract particulars (Campbell 1981). When ordinary particulars partially resemble one another by having some sparse property—say, their mass—in common, then there are distinct, exactly resembling, mass tropes as constituents of each. On a trope theory sparse properties can be identified with maximal classes of exactly resembling tropes (perhaps including merely possible tropes). Exact resemblance between tropes is taken as primitive by trope theory; but it is a simple and natural primitive compared to the partial resemblance relation taken as primitive by an adequate resemblance nominalism.

A possible disadvantage of a universals theory is that it requires two fundamentally distinct kinds of entities: universal and particulars. An ordinary particular cannot simply be identified with a bundle of coinstantiated universals, lest numerically distinct but qualitatively identical particulars be identified with one another. On a universals theory there must be some nonqualitative, nonrepeatable constituent of ordinary particulars to ground their numerical identity. A trope theory, on the other hand, needs only tropes to make a world. Ordinary particulars can be identified with bundles of coinstantiated tropes; numerically distinct but qualitatively identical

particulars are then bundles of numerically distinct but exactly resembling tropes.

The great advantage of a universals theory is that it promises to analyze all resemblance in terms of identity: Exact resemblance is identity of all qualitative constituents; partial resemblance is partial identity, identity of at least one qualitative constituent. But it is unclear whether the promise can be kept. Objects instantiating different determinates of a determinable—such as unit-positive and unit-negative charge—seem to partially resemble one another by both being charged without there being any analysis of this resemblance in terms of the identity of constituent universals or, for that matter, the exact resemblance of constituent tropes. A universals theory and a trope theory would then have to fall back upon primitive partial resemblance between universals, or tropes. Some of the advantages of these theories over resemblance nominalism would be forfeited.

Of the three basic theories of sparse properties—resemblance nominalism, a theory of immanent universals, and a theory of tropes—only one can be true; the theories posit incompatible constituent structure to the world. However, assuming each theory is internally coherent, and adequate to the needs of science, the question arises, What sort of evidence could decide between them? It seems that a choice between the theories will have to be made, if at all, on the basis of pragmatic criteria such as simplicity, economy, and explanatory power. There is as yet no philosophical consensus as to what that choice should be.

Phillip Bricker (1996)

PROPERTY

The institution of property has interested social philosophers in part, at least, because it raises issues of justice. Like government, it is practically universal but varies enough in its particular arrangements to suggest the question What criteria are relevant in assessing the relative merits of various arrangements? Again, because it discriminates between rights and fortune, it invites moral criticism and the demand for justification.

Many of the classical accounts of the origin and function of private property have taken for granted that in nature all things were held "in common." This phrase, however, is ambiguous, for it often meant not a system regulating the use of goods by general agreement but a condition where, there being no rules, everything was *res nullius* (a thing belonging to no one) and the concept "property" was consequently irrelevant. How, then, it was asked, would humans come to appropriate the land and its fruits? How could such appropriation be justified? What would be rational grounds for claiming exclusive possession? And could there be any limit on people's right to do what they would with their own?

THEORIES OF PROPERTY

According to the Church Fathers, property was both the consequence and the social remedy for the sin of covetousness that came with the Fall. But since owners have appropriated what at one time belonged to all, they have a duty to administer it for the benefit of all. “Our property,” said Gregory the Great, “is ours to distribute, but not ours to keep.” The concept of the owner as steward is the core of the traditional Christian view of property.

NATURAL LAW AND CONVENTIONALISM. By the seventeenth century, property rights came to be grounded in the needs and accomplishments of the individual owner, and ownership implied a natural right to enjoy and dispose of its objects, limited only by the duty to respect the rather narrowly defined interests of others. In John Locke’s account, property as an institution is explained by human needs. Although God gave the earth and all its fruits to all people to preserve their lives, still this meant one’s making the fruits of the earth exclusively his own, if only by eating them. However, what in nature entitled one to call something one’s own was that one made the effort to make it so. To add one’s labor to a *res nullius* was to create a title to the whole product. Locke limited this title to whatever one could use before it spoiled; appropriation for waste would be illegitimate.

To appropriate an object implied for Locke not merely a right to enjoy it but also to alienate it at will, so that although the appropriation of *res nullius* could legitimately be effected only by labor, the title, once established, could be freely transferred. It is questionable, however, whether Locke was justified in assuming that because we may appropriate what we need from the common stock, we may therefore transfer what we acquire, but do not need, to whomsoever we choose. Locke needed this right, however, if his theory was not to suggest, as did certain later writers on economic justice, that the laborer was entitled to the entire fruits of his master’s fields, if not to the fields themselves. For where all land had long been appropriated, the titles of present owners would depend entirely on the legitimacy of such transfers in the past. So, since the land was no longer *res nullius*, all the laborer could claim was the value of his labor in wages. Moreover, in a market economy and with the introduction of money, wealth might be accumulated and stored indefinitely without spoiling; furthermore, since money had only a conventional value, hoarding it deprived no one of anything of natural value, and its distribution must be taken to be by common consent. Having accounted, then, for the existence of property, and for

existing titles, with a theory of natural right, Locke overlaid the theory with a conventionalist theory that neutralized the limitations on appropriation that the original theory prescribed.

Nature and convention are to be found similarly blended, if in varying proportions, in Hugo Grotius, Samuel von Pufendorf, and William Blackstone. In Immanuel Kant, too, there is a blend. Kant deduced the principle of first occupier from the autonomy of the will but conceded that only a universal legislative will—the civil state—could give binding force to the intention to appropriate.

UTILITARIAN POSITIONS. According to David Hume, a man’s creation ought to be secured to him in order to encourage “useful habits and accomplishments.” Inheritance and the right to alienate were alike valuable as incentives to or conditions for useful industry and commerce. Property rested on convention in the sense of rules upheld by common interests commonly perceived. It was a law of nature, too, but in the sense that men were sufficiently alike the world over for the same general arrangements to be equally to the public advantage. Hume’s argument, then, also blends natural law doctrine with conventionalism but reduces both to utilitarianism.

Jeremy Bentham did little more than elaborate Hume’s arguments. However, by introducing considerations of utility, Hume and Bentham pointed the way for criticism of the distribution of private property and, indeed, of the institution itself. Already in 1793 William Godwin was arguing that in a consistent application of the principle of utility “every man has a right to that, the exclusive possession of which being awarded to him, a greater sum of benefit or pleasure will result, than could have arisen from its being otherwise appropriated” (*Political Justice*, Book 8). J. S. Mill, though broadly committed to a belief in private property, held that, in the case of land at any rate, private ownership must be conditional on its expediency; the rights associated with it, especially the right to exclusive access and enjoyment, ought to be limited to whatever was required to exploit it efficiently. Mill recognized that the rights of property were not an inseparable bundle, to be justified en bloc; each constituent right had to be independently justified on grounds of utility.

However, Mill’s belief that the institution of property would be justified provided that it guaranteed to individuals the fruits of their labor and abstinence is open to question. In a complex industrial society, “the fruits of one’s labor” can mean only the value of a given worker’s

contribution to the finished product. But value derives from the relations of supply and demand, both for the commodity and for labor of the various kinds needed to produce it. “The fruits of one’s labor,” understood as one’s share in a social dividend, will depend not only on one’s efforts but also on the number of other people available to do the same job and on how badly consumers want it done. If for the time being a particular skill is in short supply, is it self-evident that this increases the value of its fruits or that those who have it should be the better off for it?

MARXIST AND HEGELIAN CRITIQUES. Again, the exclusive claims of labor take no account of what men owe to others and to the social interest. Émile Durkheim, for instance, objected that “it is not enough to invoke the rights that man has over himself: these rights are not absolute but limited by the claims of the moral aims, in which a man has to cooperate.” Karl Marx was equally critical of the German Social Democrats’ Gotha program of 1875, which claimed that labor should receive its produce “unabridged and in equal right.” He charged that this formula ignored the need for capital replacement and development, social services, and the support of the incapable. In any case, he said, distribution proportional to contribution would still be only partial justice, bearing in mind differences in natural capacity on the one hand and need on the other. In the truly cooperative society, based on common ownership of the means of production, individual labor would be impossible to separate out, and distribution would be according to need alone. This would be possible, however, only because labor would have ceased to be a burden and would have become “life’s principal end.”

This last condition suggests why, in a period when hedonistic premises underlay a great deal of psychology, ethics, and economics, the necessary relation between labor and property should have been so generally accepted. On the assumption that work was painful, the only conceivable reason for working was a greater pleasure expected from its fruits. Marx argued that this account of labor was neither an explanation nor a justification, but a consequence, of the system of private property. The worker was alienated from his work, which appeared to him not as a fulfillment but as a burden; he was alienated, too, from the product of his work, which, passing to his employer in surplus value, confronted him as capital—that is, as an instrument of his own bondage.

Despite the stress on labor as the source of value that Marx shared with the English utilitarians and econo-

mists, his account of property derives at least as much from G. W. F. Hegel as from the English school. Like Kant, Hegel regarded property as necessary not because it helped to satisfy human needs but because “a person must translate his freedom into an external sphere in order that he may achieve his ideal existence” (*Philosophy of Right*, Sec. 41); because “property is the first embodiment of freedom and so is in itself a substantive end” (Sec. 45). Plato erred, in Hegel’s view, in denying private property to the guardians, for he was denying them the conditions necessary for giving concrete realization to their personalities and wills.

Marx and Hegel are alike in seeing the human will objectifying itself in its acquisitions and creations. If for Marx the process is not rationalizing and liberating but alienating and enslaving, it is because the property created is not and cannot be the worker’s own. The laborer can transcend this alienation only in the communist society, in which, like Plato’s guardians or the members of a monastic community, he gets caught up in a common enterprise where “mine” and “thine” are of no account because life is more than the satisfaction of material needs. In a world in which “sharing in” counted for more than “sharing out,” property—like justice—would present no problems.

ECONOMIC AND SOCIAL SIGNIFICANCE. In the course of the past century, legal and social philosophers (Léon Duguit and Karl Renner, for example) have come to think of property increasingly as an institution with social functions and not, like Locke, as simply a guarantee of individual interest. Moreover, because property entails inequalities in power, in claims on the social product, in social status, and in prestige, it must be justified, and not merely in terms of the interests or natural rights of its immediate beneficiaries.

It is difficult, however, to see how any one theory could apply generally to all forms of private property and include all rights of ownership. Individual control of productive resources raises very different issues from the exclusive right to enjoy consumer goods such as clothes and furniture. The right to control the use of mines and factories is not really an instance of the right of a Kantian rational and autonomous being to manipulate mere things for his own needs; it is also an exercise of power over other people. According to A. A. Berle, the United States is gradually extending to such property the limitations traditionally applied to state action in order to protect individual freedom.

Again, could one justify one's title to dividends on the ground that instead of enjoying the fruits of one's labor one had invested them? And would the same justification extend to a corporate title to the yield on investments financed out of undistributed profits? Such claims have certainly flourished under the umbrella of natural rights; but it is difficult to see how any but a utilitarian argument could seriously be proposed in defense of such arrangements.

ANALYSIS OF OWNERSHIP

Talk of property often seems to be talk about things. Things constitute property, however, only inasmuch as they can be assigned to owners; to own something is to have, in respect to it, certain rights and liabilities vis-à-vis other persons or the public at large. Ownership, therefore, is a normative relation or a complex of such relations between owner, object, and third parties, and to refer to something as "property" is to locate it as a term in such a relationship. Some jurists, indeed, insist that *property* refers not to things at all but, rather, to a bundle of rights. And this is obviously true of income titles, such as securities and annuities, and of rights of control over "intellectual property," such as patent rights and copyrights; these are "things" only in a very abstract sense, as characteristic complexes of normative relations.

As the objects of property are diverse, so also are the rights constituting it. Landowners' rights are necessarily different from copyright owners', and the owner of a gun does not have the same unrestricted use and control of it as the owner of a table has of the table. Jurists have nevertheless tried to identify some right necessary to ownership. The rights of exclusive use, possession, or alienation seem to be likely candidates, but each can conceivably be detached (for example, by a lease or an easement, under the terms of a trust, or, in former times, by entail) without the owners' losing property in the object. Accordingly, Sir Frederick Pollock suggested that "we must look for the person having the residue of all such powers when we have accounted for every detached and limited portion of it." But this residue, as held, say, by a ground landlord with a thousand-year tenant, may be very slender indeed, and the owner to whom all the detached rights will revert when the encumbrances reach the end of their term will certainly not be the present owner.

A. M. Honoré suggests a way out of these difficulties by concentrating not on the difficult exceptions but on the standard instance. He defines ownership as "those legal rights, duties and other incidents which apply, in the ordinary case, to the person who has the greatest interest

in a thing admitted by a mature legal system." Among the characteristic features are the right to possess and to be secure in possession, to use and to manage the property, to enjoy income arising from it and to alienate, consume, waste, or destroy the capital, and to transmit ownership to one's successors indefinitely; the absence of a fixed date on which the owners' interests terminate; the prohibition of harmful use; the liability of the property to execution for debt or insolvency; and the reversion to the owner on the termination of whatever lesser interests (leases, usufructs) encumber the property. Now, to say that *A* is the owner of *x* is not necessarily to say that he is the present subject of all these incidents; however, provided the kind of property in question can intelligibly be said to be the object of them and in the absence of special conditions or reservations, it is reasonable to infer that he is.

The Scandinavian legal realists—Karl Olivecrona and Alf Ross, for example—have been more radical in their analyses. According to Ross, ownership is "solely ... a tool in presentation." Theoretically, one could enunciate a mass of directives to judges, each consisting of a conditioning fact or facts (*F*) and a legal consequence (*C*), such as (1) if a person has lawfully purchased a thing (F_1), judgment for recovery of possession should be given in his favor (C_1); (2) if a person by prescription has acquired a thing and raised a loan that is unpaid (F_2), the creditor should be given judgment for satisfaction out of the thing (C_2); and so on. Now, to introduce "ownership" is not, according to Ross, to add something that *accounts* for the connections between the *F*'s and the *C*'s but merely to indicate the systematic connection between them such that $F_1, F_2, F_3, \dots, F_p$ severally and collectively entail the totality of legal consequences $C_1, C_2, C_3, \dots, C_n$. The word *ownership* in Ross's view is "without any semantic reference whatever"; it serves only to reduce the complexity of particular rules to a systematic order. There is nothing beyond or in addition to the rules.

Now, it is certainly true that only confusion can result from trying to identify some special kind of a thing, or some special quality of things, which is called "property." Nevertheless, "ownership" does not always imply the same bundle of rights. The possible conditioning facts and the legal consequences are not the same for every case in which one may say that *X* is the owner of *P*. And, therefore, since the relevant rules do not have the rigorous relation to one another that Ross suggests, one can identify them as the rules of property (as distinct from, say, personal rights) only by recognizing some sort of family resemblances between them. Indeed, the terms Ross uses in exemplifying his conditioning facts—"purchase,"

“occupation of *res nullius*,” “acquisition by prescription”—are obviously already impregnated with ownership; to purchase something, for example, is to give money for it—that is, on the understanding that one acquires not merely possession, but also owners’ rights, over it.

Deciding who is the owner of a piece of property is, of course, to decide on the basis of certain facts where certain powers and liabilities lie. But to reduce a legal concept like property to a finite set of directives to judges ignores the fact that judges are constantly having to reshape the rules in the very process of applying them. If the rules of ownership are treated as a more or less arbitrary agglomeration, it is difficult to see how judges could make rational decisions at all.

Ross’s bundle of conditioning facts and legal consequences is significant, however, because it suggests how one goes about constructing a paradigm case of ownership, or, rather, a family of paradigms related by the fact that different conditioning facts entail broadly similar legal consequences. Deciding ownership in an atypical case would then involve deciding whether it can be assimilated to any of the available paradigms even though some characteristic ownership features are absent or other features that are out of character are present. A judge may have all kinds of reasons for making or refusing such an assimilation; but it is difficult to see how the problem could be presented to him at all without presupposing the standard cases of ownership as agreed starting points for discussion.

PROPERTY [ADDENDUM]

What is property? It is some valued item that belongs to someone. Its existence in society may be collective or individual, although even if collective, it usually emerges from instances of (pooled or expropriated) individual

ownership. And that presupposes the right to *private* property.

PROPERTY IS PRIVATE

The institution of the right to private property is the single most important condition for a society in which freedom in the classical liberal tradition—which means negative liberty, including free trade, freedom of the press, and freedom of religion—is to flourish. Under communism, in contrast, no such right is recognized. Privacy has a negligible role in a system which holds, as Karl Marx (1818–1883) proclaimed, that “the human essence is the true collectivity of man” (1970, p. 126). Even within noncommunist, nonsocialist systems the exact status of property is in dispute—some hold it is a convention established by implicit consensus and maintained by government or law. Some hold it is a natural normative relationship that comes about by means of the creative and productive initiative of persons and the law of property exists to recognize and not to create it.

WHAT IS THE RIGHT TO PRIVATE PROPERTY?

Karl Marx understood the right to private property, although it was John Locke (1632–1704) who tried to justify this right. Marx wrote, in “On the Jewish Question,” that “the right of man to property is the right to enjoy his possessions and dispose of the same arbitrarily without regard for other men, independently, from society, the right of selfishness” (1970, p. 53). This, though correct, is not the full story. The right to private property, be it applied to obtaining and holding a toothbrush or, as was Marx’s concern (and what Marx found objectionable), an entire factory, does spell out a person’s authority to use what he or she owns without regard for other persons. This use may be reckless, prudent, or generous. Its exercise may not, however, violate others’ rights. Defenders do not assume that it would be insidious.

The natural right to private property was only discussed in direct terms starting in the eleventh and twelfth centuries. William of Ockham (1285–1347) proposed that “Natural right is nothing other than a power to conform to right reason, without an agreement or pact” (2001, p. 48) or, as Heinrich A. Rommen paraphrased him, “the right to private property is a dictate of right reason” (1954, p. 419), the power to make one’s moral choices on one’s own, free of others’ intrusion. Because such choices are made by persons in the natural world, one of our natural rights is the right to private property.

ONE ROLE OF PRIVATE PROPERTY IN SOCIETY

Property rights weren’t explicitly identified in ancient times but the Old Testament ban on stealing implies what was spelled out by Locke and other classical liberals. Moreover, there have been strong philosophical intimations of it in, for example, Aristotle’s *Politics* (384–322 BCE). Whereas Plato, his teacher, held that, at least within the ruling class of a political community, there may not be any private property and indeed privacy, at all, Aristotle objected as follows:

That all persons call the same thing mine in the sense in which each does so may be a fine thing, but it is impracticable; or if the words are taken in the other sense, such a unity in no way conduces to harmony. And there is another objection to the proposal. For that which is common to the greatest number has the least care bestowed upon it. Every one thinks chiefly of his own, hardly at all of the common interest; and only when he is himself concerned as an individual. For besides other considerations, everybody is more inclined to neglect the duty which he expects another to fulfill; as in families many attendants are often less useful than a few. (*Politics*, 1261b34)

Earlier Thucydides (c. 471–c. 400 BCE) said,

They devote a small fraction of the time to the consideration of any public object, most of it to the prosecution of their own objects. Meanwhile, each fancies that no harm will come to his neglect, that it is the business of somebody else to look after this or that for him; and so, by the same notion being entertained by all separately, the common cause imperceptibly decays. (*The History of the Peloponnesian War*, bk. 1, sec. 141)

So, communal ownership leads to reduction of responsibility and a corresponding lack of attentive involvement with whatever is owned. This does not mean that people are evil. At their homes, this is likely to be different—if one is late and rushes off, the trash will be disposed of upon one’s return. At a public place the attitude seems to be, “It will get cleaned up somehow, by someone, at some time.” So, it is a systemic problem: people are unable to incorporate the significance of managing the public property within the scale of their values. Each of us knows, directly, how important or not it is for oneself to keep one’s backyard clean. So one will take care of it commensurate with that knowledge. It is not possible, however, for an individual to know how important it is for the

community, society, or humanity at large that one keep the air or river or lake clean, and to what degree.

A more recent defense of the right to private property is closer to that which we get from John Locke; namely, that we require this right so as to have a sphere of moral authority—as Robert Nozick (1938–2002) called it, “moral space,” or as Ayn Rand (1905–1982) noted,

Bear in mind that the right to property is a right to an action, like all others: it is not the right to an object, but to the action and the consequences of producing or causing that object. It is not a guarantee that a man will earn any property, but only a guarantee that he will own it if he earns it. It is the right to gain, to keep, to use and to dispose of material values. (1967, p. 322)

Basically, then, the main normative reason given for why one has a right to private property is that it is the means by which one’s liberty to act free of others’ imposition is secured within a social context. It is also a precondition for individuals to act prudently and productively in human communities without the legal permission for others to take from them what they have earned. Economists tend, in contrast, to defend it as a feature of the infrastructure by which productivity and prosperity is best encouraged in a society. Another support given to the idea is that it makes it possible for individuals to remain sovereign and to distribute resources as they see fit rather than others would demand.

There are innumerable objections to the right to private property, most recently the idea that property is held by the public at large and government merely permits individuals to make use of it to the extent government deems this in the public interest. For why this is a troublesome view the general theory of natural rights would need to be explored and scrutinized.

PROPOSITIONAL ATTITUDES: ISSUES IN SEMANTICS

Propositional attitudes like knowledge, belief, and assertion play an important foundational role for semantic theory, the goal of which is to specify the meanings of sentences and their semantic contents relative to contexts of utterance. Meanings are plausibly regarded as functions from such contexts to semantic contents, which in turn are closely related to the assertions made, and the beliefs expressed, by utterances. For example, the semantic content of *I live in New Jersey* in a context *C* with *x* as agent and *t* as time is standardly taken to be the proposition that *x* lives in New Jersey at *t*. To understand the meaning of this sentence is, to a first approximation, to know that a competent speaker *x* who sincerely and assertively utters it in *C* asserts, and expresses a belief in, this proposition. Roughly put, if *p* is the semantic content of *S* in *C*, then an assertive utterance of *S* in *C* is an assertion of *p*, and is standardly taken as indicating the speaker’s belief in *p*. Whether the semantic content of a sentence is always among the propositions asserted by an utterance of the sentence, and whether, in those cases in which it is, the assertion of any other proposition by the utterance is always parasitic on the assertion of the semantic content, are matters of detail. Though important, they do not affect the foundational point. A semantic theory for a language is part of a larger theory that interprets the assertions and beliefs of its speakers. This, more than any other fact, allows one to subject semantic theories to empirical test. Competent speakers of a language are relatively good at identifying the propositions

asserted and beliefs expressed by utterances. To the extent to which assignments of semantic content issued by a semantic theory lead to verifiably correct characterizations of speakers' assertions and beliefs, the semantic theory is confirmed; to the extent to which these assignments lead to verifiably incorrect characterizations, it is disconfirmed.

ATTITUDE ASCRIPTIONS

This point is closely related to the use of attitude ascriptions

(1a) N asserted that S

(1b) N believed that S

to test different semantic analyses of S. It is convenient to express this in terms of the relational nature of the attitudes. Consider assertion. In each case of assertion there is someone, the agent, who does the asserting, and something, the object of assertion, that is asserted. The term *proposition* is used to designate things that are objects of assertion (and other propositional attitudes) and bearers of truth value. Assertion is a mediated relation holding between agents and propositions. An agent asserts a proposition *p* by doing something or employing some content-bearing representation associated with *p*. The most familiar cases are those in which the agent asserts a proposition by assertively uttering a sentence.

Ascriptions like those in (2) report the assertions of agents:

(2a) Edward asserted the proposition that Martha denied.

(2b) Edward asserted the proposition that the Earth is round.

(2c) Edward asserted that the Earth is round.

That in (2a) *asserted* is flanked by two noun phrases suggests that it is a two-place predicate and that a sentence 'NP assert NP' is true if and only if the first (subject) noun phrase designates an agent who bears the assertion relation to the entity designated by the second (direct object) noun phrase. This analysis also applies to (2b), which is true if and only if Edward asserted the proposition designated by *the proposition that the Earth is round*. On the assumption that this proposition is also designated by *that the Earth is round*, this analysis can be extended to (2c), which is equivalent to (2b). Similar remarks hold for other propositional attitude verbs, including *believe*, *deny*, *refute*, and *prove*.

With this in mind, one can return to the ascriptions in (1). If, as many theorists believe, (i) 'that S' in (1) designates the semantic content of S (in the context), (ii) these ascriptions report relations between agents and those contents, and (iii) sometimes substitution of sentences with necessarily equivalent semantic contents fails to preserve the truth values of such ascriptions, then semantic contents must be more fine-grained than the sets of possible world-states in which they are true. On these assumptions substitution in such ascriptions can be used to discriminate different but intensionally equivalent semantic analyses of S.

PROPOSITIONS, POSSIBLE WORLD-STATES, AND TRUTH SUPPORTING CIRCUMSTANCES

This has significance for possible world semantics. In this framework a semantic theory is a formal specification of truth with respect to a possible context of utterance and circumstance of evaluation. The semantic content of S in C is the set of possible circumstances E such that S is true with respect to C and E. Circumstances of evaluation are traditionally identified with possible world-states—thought of as maximally complete properties that the world genuinely could have had. As a result, the semantic contents of all necessarily equivalent sentences are taken to be identical. This, plus the standard treatment of attitude ascriptions as reporting relations between agents and the semantic contents of their complement clauses, leads to the counterintuitive prediction that substitution of necessarily equivalent sentences in such ascriptions never changes truth value. If one adds the apparently obvious fact that (3a) entails (3b),

(3a) A asserts/believes that P&Q

(3b) A asserts/believes that P&A asserts/believes that Q

one gets the further counterintuitive results (i) that anyone who asserts or believes a proposition *p* asserts or believes all necessary consequences of *p*, and (ii) that no one ever asserts or believes anything necessarily false, since to do so would involve simultaneously asserting or believing every proposition.

In 1983 Jon Barwise and John Perry attempted to evade these results by constructing a semantic theory in which metaphysically possible world-states were replaced by abstract situations—thought of as properties that need be neither maximally complete, nor genuinely capable of being instantiated by any parts of the world. This strategy was shown to be unsuccessful by Scott Soames (1987),

where it was demonstrated that variants of the problems posed by attitude ascriptions for standard possible worlds semantics can be re-created for any choice of truth-supporting circumstances used in formal characterizations of truth with respect to a context and a circumstance. Robert C. Stalnaker explored a different approach in 1984. After providing a naturalistic argument that semantic contents must be sets of metaphysically possible world-states, he suggested that counterexamples could be avoided by (i) allowing for exceptional cases in which attitude ascriptions report relations to propositions other than those expressed by their complement clauses, and (ii) resisting the claim that the agent believes the conjunction of *p* and *q* in many cases in which the agent believes both conjuncts. These suggestions are rebutted in later work by Mark Richard (1990) and Jeffrey Speaks (forthcoming).

STRUCTURED PROPOSITIONS, MILLIANISM, AND DESCRIPTIVISM

The problems posed by attitude ascriptions for possible worlds semantics have led many theorists to characterize the semantic content of a sentence *S* as a structured complex the constituents of which are the semantic contents of the semantically significant constituents of *S*. In essence this was also the classical position of Gottlob Frege (1892/1948) and Bertrand Russell (1905, 1910). A variant of this position, growing out of the possible worlds framework, was championed by Rudolf Carnap (1947). For Carnap, two formulas are intensionally isomorphic if and only if they are constructed in syntactically the same way from constituents with the same intensions (functions from world-states to extensions). In effect, semantic contents of syntactically simple expressions are identified with intensions, while semantic contents of syntactically complex expressions are structured complexes the constituents of which are the semantic contents of their grammatically significant parts. This view was criticized by Alonzo Church (1954), who argued that semantically complex, but syntactically simple, expressions require a stronger notion of synonymy than sameness of intension. Church's modification of Carnap—which relies on rules of sense to induce a notion of synonymous isomorphism—is a variant of the classical Fregean position.

In the late 1980s the assignment of structured semantic contents to sentences was given a neo-Russellian twist by David Kaplan (1986, 1989), Nathan Salmon (1986), and Soames (1987). On the Russellian picture structured propositions are recursively assigned to formulas, relative

to contexts and assignments of values to variables. The semantic content of a variable *v* relative to an assignment *f* is just *f*(*v*), and the semantic content of a closed (directly referential) term relative to a context *C* is its referent relative to *C*. Semantic contents of *n*-place predicates are *n*-place properties and relations. The contents of truth-functional operators may be taken to be truth functions, while the semantic content of a formula $\ulcorner \lambda x [Fx] \urcorner$ is identified with a propositional function *g* that assigns to any object *o* the structured proposition expressed by $\ulcorner Fx \urcorner$ relative to an assignment of *o* to "*x*." $\ulcorner \exists x [Fx] \urcorner$ expresses the structured proposition in which the property of assigning a true proposition to at least one object is predicated of *g*. In this framework the attitude ascriptions (1a and 1b) express structured semantic contents in which the relation of asserting or believing is predicated of a pair consisting of an agent and the structured proposition semantically expressed by *S*. The semantic theory is completed by specifying the intensions determined by structured semantic contents, including the truth conditions of structured propositions in all possible world-states.

The signature commitment of this approach is to the possibility of asserting and believing singular propositions—which include as constituents the very objects they are about. On this approach to believe *de re* of an object that it is *F* is to believe the singular proposition about that object, which says that it is *F*. Sentences like (4), involving quantifying-in, are quintessential examples of *de re* belief ascriptions.

- (4) There is a planet *x* such that when the ancients saw *x* in the morning they believed that *x* was visible only in the morning and when they saw *x* in the evening they believed that *x* was visible only in the evening.

MILLIANISM. If, as Kaplan (1989) contends, the semantic contents of sentences containing indexicals are also singular propositions, then belief ascriptions containing indexicals in their complement clauses are also *de re* and hence share the basic semantic properties of ascriptions like (4). Salmon (1986) and Soames (2002) take this a step further, arguing for the Millian view that the semantic content of an ordinary proper name is simply its referent. One potentially problematic consequence of this view is that since *Ruth Barcan* and *Ruth Marcus* are coreferential, (5a) is characterized as semantically expressing the same proposition as (5b) and hence as having the same semantically determined truth value, even though it seems evident to many that it is possible to believe that

Ruth Barcan was a modal logician without believing the
Ruth Marcus was:

(5a) John believes that Ruth Barcan was a modal logician.

(5b) John believes that Ruth Marcus was a modal logician.

Different Millians respond to this problem in different ways. Salmon (1986) and David Braun (2002) argue that the intuitions that (5a) and (5b) can differ in truth value are mistaken because speakers tend to confuse the identical beliefs ascribed to John by these ascriptions with the different manners of holding these beliefs associated with their different sentential complements. Soames (2002, 2005a) argues that even though the semantic contents of these sentences are the same, assertive utterances of them may indeed result in assertions of propositions with different truth values. In “A Puzzle about Belief” (1979) Saul Kripke takes a different tack. While neither advocating nor denying the Millian view, he argues that substitutivity problems of the sort illustrated here are independent of Millianism and indicate a breakdown of the basic principles underlying our belief-reporting practices.

DESCRIPTIVISM. By contrast, descriptivists, following in Frege’s footsteps, have wanted to assign different semantic contents to the two names and hence to the complement clauses in (5a and 5b). The problem has been to find a way of doing this that does not run afoul of Kripke’s refutation of descriptivism in *Naming and Necessity* (1972). One of Kripke’s arguments holds that since names are rigid designators, their semantic contents cannot be given by any nonrigid descriptions. This argument is not easily avoided by rigidifying candidate descriptions. As shown by Soames (2002), an analysis that takes the semantic content of *Aristotle* to be given by ‘the actual F’ will, all other things being equal, identify the semantic content of *Aristotle was a philosopher* with the singular proposition (about the actual world-state @) that the unique individual who “was F” in @ was also a philosopher. Assuming that the analysis also includes the standard relational treatment of belief ascriptions, one then gets the result that for any possible agent *a* and world-state *w*, ‘*x* believes that Aristotle was a philosopher’ will be true of *a* with respect to *w* only if in *w* *a* believes that the unique individual who “was F” in @ [not *w*] was also a philosopher. Since this is obviously incorrect, names can neither be nonrigid descriptions, nor descriptions rigidified using the actuality operator.

What about descriptions rigidified using Kaplan’s *dthat* operator? Even if, contra Kripke, a correct reference-fixing description ‘the *x*: *Dx*’ could be found for each name, the semantic content of ‘*dthat* [the *x*: *Dx*]’ would simply be its referent, in which case the descriptivist would be saddled with precisely the Millian predictions about attitude ascriptions that the theory was designed to avoid. One possible response, suggested by David Chalmers (2002), is, in effect, to take a belief ascription ‘*a* believes that *S*’ to report that the belief relation holds between the agent and pair consisting of the semantic content of *S* (in the context) and the meaning (function from contexts to such contents) of *S*. However, now a different problem arises. To avoid Kripke’s non-modal arguments against familiar candidates for reference-fixing descriptions, post-Kripkean descriptivists have had to resort to egocentric, metalinguistic descriptions of the sort *the individual I have heard of under the name “n.”* Although this move assigns different objects of belief to the complement clauses of (5a) and (5b), it does not solve the problem. The point, after all, is not simply to assign different belief objects in these cases, but to explain the different information one gathers about John from utterances of (5a) and (5b). As Soames (2005b) argues in *Reference and Description: The Case against Two-Dimensionalism* (2005), it is hard to see how these egocentric, metalinguistic descriptions could, realistically, contribute to this.

DAVIDSON’S LINGUISTIC VIEW

A different approach to problems involving substitutivity is to take ascriptions ‘*x* says/asserts/believes that *S*’ as reporting relations either to *S* itself, or to a complex in which *S* is paired with its semantic content. Either way, since substitution of one expression for another in *S* always produces a new complement *S*’, attitude ascriptions that differ in this way always report relations to different objects, whether or not the semantic contents of *S* and *S*’ are the same. This encourages the thought that such ascriptions can always differ in truth value.

An early and influential version of this approach was developed by Donald Davidson (1968–1969), who argued that (6a) should be understood on the model of (6b), in which *that* is treated as a demonstrative, utterances of which refer to utterances of the independent sentence that follows it:

(6a) Galileo said that the Earth moves.

(6b) Galileo said that. The Earth moves.

On this analysis what is said by an assertive utterance *u* of (6a) is that one of Galileo's utterances stands in, as Davidson puts it, the samesaying relation to the subutterance *u** of *the Earth moves*. Although this analysis promised a simple way of capturing the logic of attitude ascriptions, it foundered on certain recalcitrant facts, including the fact that some ascriptions, like *Every mother said that her son was lovable*, cannot be broken up into separate and independent sentences in the manner of (6b) and the fact that the assertion made by an utterance of (6a) could have been true even if the subutterance *u** had never existed, indicating that the Davidsonian truth conditions are incorrect.

LATER LINGUISTIC AND REPRESENTATIONALIST VIEWS

Beginning in the 1990s improvements of Davidson's idea, including, most notably, that of Richard Larson and Peter Ludlow (1993), avoid these difficulties by dispensing with utterances and by treating attitude ascriptions as reporting relations between agents and the interpreted logical forms of their sentential complements. These are abstract, syntax-encoding structures that contain both the expressions occurring in sentences and their referential contents. Abstracting, one has here a version of the structured propositions approach in which linguistic expressions are included in the propositions sentences express. Although this version has potential virtues, it shares a crucial problem with Davidson's original analysis. Just as Davidson's silence about the intension of the samesaying relation prevented his theory from making any predictions about when (if ever) substitution of coreferential names or indexicals in a *says that* ascription changes truth value, so Larson and Ludlow's silence about the intension of the belief relation, alleged to hold between agents and interpreted logical forms, prevents their theory from making any predications about similar substitution in belief ascriptions (see Soames 2002). Since some such substitution clearly does preserve truth value, the problem is a daunting one.

Arguably, the most sophisticated approach of this general type is Richard's (1990), which combines context-sensitivity with linguistically augmented, structured Russellian propositions. For Richard, a belief ascription 'x believes that S', used in a context C, is true of an agent *a* if *a* accepts some sentence S' with the same Russellian content in *a*'s context as S has in C, while being similar enough to S to satisfy the belief-reporting standards in C. As indicated by Soames (2002), the evaluation of this view crucially depends on identifying similarity stan-

dards present in contexts and assessing their impact. Although there are certain evident problems here, opinions of their import vary. Finally, a different sort of context-sensitive view, advocated by Mark Crimmins and John Perry (1989), takes belief ascriptions to report that an agent believes a structured, Russellian proposition by virtue of having ideas of a certain sort—where these are mental particulars in the mind of the agent that are either implicitly demonstrated, or implicitly characterized as being of a certain type, by the one uttering the ascription. This view is usefully criticized by Jennifer Saul (1993).

EXTENSION: INTENSIONAL "TRANSITIVE" VERBS

Example (2a), in which *assert* occurs as an ordinary transitive verb operating on the extensions of its noun-phrase arguments, shows that not all attitude ascriptions contain sentential clauses. The examples in (7) show that there are also verbs, the grammatical objects of which are not overtly clausal, which are intensional in nature:

- (7a) John wants a perpetual motion machine.
- (7b) John is looking for the fountain of youth.
- (7c) John imagined a room full of unicorns.
- (7d) John worships many gods.

The relationship between these examples and ordinary propositional attitude ascriptions is a matter of ongoing investigation. How is it that (7a to 7d) can be true even though there are apparently no real entities described by their postverbal arguments? Are some or all these sentences covertly clausal? For example, are (7a) and (7b) to be assimilated to (8a) and (8b)?

- (8a) John wants it to be the case that he has a perpetual motion machine.
- (8b) John is trying to bring it about that he finds the fountain of youth.

These and related questions have been discussed by philosophical logicians and linguistic semanticists including Richard Montague (1974), Graeme Forbes (2000), Richard (1998), and Marcel den Dikken, Larson, and Ludlow (1997).

PROPOSITIONAL ATTITUDES: ISSUES IN THE PHILOSOPHY OF MIND AND PSYCHOLOGY

This entry aims to characterize the philosophical issues surrounding the propositional attitudes. Particular attention is paid to the arguments philosophers have brought to bear when discussing the existence and nature of the attitudes.

SUBJECT MATTER AND PHILOSOPHICAL METHODOLOGY

Discussions of the nature of mind typically distinguish between two fundamental kinds of mental states or properties. One kind of mental state or property involves states that are qualitative in nature: Examples include raw feels, sensations, tickles, and pains. The other kind of mental state or property involves states that are contentful in nature, "pointing to" or "representing" things beyond themselves: Examples include thoughts, desires, fears, and intentions. This distinction is not unproblematic, since it is not clear whether these two categories exhaust the domain of the mental, nor is it clear whether they are mutually exclusive. However, most philosophers of mind accept that there is some important distinction in this region. Propositional attitudes are often cited as the paradigmatic example of the latter kind of mental state.

As their name indicates, the propositional attitudes are *attitudes*—cognitive relations such as belief, desire, fear, hope—that a subject bears to what are typically (though not uncontroversially) taken to be *propositions*. The attitudinal component of a propositional attitude is

a matter of how a particular proposition is being taken: Thus Sally can *believe* that it will rain, *hope* that it will rain, *fear* that it will rain, and so forth. In each case the proposition that is the content of her attitude, *that it will rain*, is the same; what differs is how this proposition is being taken by Sally (believed in, hoped for, or feared). Of course, one and the same attitude can be taken towards different propositions: Thus Sam can believe that the Yankees are a great baseball team, believe that Atlanta is hot and muggy, believe that the office of the U.S. presidency has been demeaned, and so forth. In each case Sam's attitude is the same (belief), what differs is the propositions he believes.

A good deal of the attention philosophers have given to the propositional attitudes is devoted to analyzing the sentences used to ascribe the attitudes. Examples of such *attitude-ascribing sentences* include "Jones believes that it's raining," "Smith worries that State University's soccer team will lose," and "McSorley wants State University's soccer team to lose." Indeed, the very idea that propositional attitudes are cognitive relations that subjects bear to propositions (a variant of which is defended in Jerry Fodor's 1978 article, "Propositional Attitudes") is advanced on the basis of the surface grammar of the sentences used to ascribe the attitudes. Thus "Jones believes that it's raining" is naturally read as saying, of Jones (the reference of "Jones"), that he bears the belief-relation (= the reference of "believes") to the proposition *that it's raining* (= the reference of "that it's raining"). Even sentences such as "McSorley wants State University's soccer team to lose," which do not appear to refer to a proposition at all, can be translated (admittedly with some awkwardness) into equivalent sentences that do, or at least appear to, make such a reference: "McSorley wants it to be the case that State University's soccer team loses." Admittedly, though, such a propositionalist formulation may not be possible in all cases of attitude-ascribing sentences. Consider "Williams fears bats" or "Simon loves ice cream."

Whatever their ultimate nature (more on which below), the propositional attitudes themselves have been thought to be extremely important for the study of human behavior. This is seen when we consider how we go about explaining our own and others' behavior in those cases in which the behavior is taken to be intentional (falling in the domain of human action). In such cases, we explain the behavior as the effect of the subject's propositional attitudes. Thus it seems natural to explain why McSorley walked to the refrigerator in terms of her desire for cold water and her belief that cold water is to be

found there; or to explain why Jackson ran away by citing his belief that a dangerous lion was coming his way and his desire not to get attacked. Explanations of this belief-desire sort are used by ordinary folk as we go about trying to predict and explain the actions of our fellows in everyday circumstances.

One philosophical question that arises in this connection concerns the status of such explanations. Suppose, as many philosophers do, that these explanations are sometimes true. What sort of explanation do they offer? Perhaps everyone can agree that they are *rationalizing* explanations, depicting the action in question as rational in light of the subject's corpus of beliefs and desires. But some philosophers hold that, in addition to rationalizing the behavior in question, they also provide a *causal* explanation of it (see Davidson 1963). If so, then the sort of psychology that appeals to the ordinary "folk" explanations of action—what has been termed *folk psychology*—can take its place beside other sciences that seek to characterize the world's causal nexus.

It is noteworthy that the causal-explanatory perspective provides an alternative approach to the nature of the attitudes, one that differs from the approach involving the analysis of attitude-ascribing sentences. Where the sententialist approach (as we might call it) assumes that we can understand the attitudes by making sense of *our talk* about them, the causal-explanatory approach begins by assuming that, whatever their ultimate nature, the propositional attitudes are the causal springs of human action. Taking the latter approach leads one to conceive of the attitudes as whatever plays the relevant causal role in the production of action. Of course, the two approaches might well be complementary: What one learns about the attitudes from analyzing attitude-ascribing sentences might be compatible with (and supplement) what one learns about the attitudes by thinking about them as the causal basis of action. (Indeed, the desire to secure the compatibility of the sententialist approach and the causal-explanatory approach appears to be a core motivation behind Fodor's 1975 hypothesis in *Language of Thought*, according to which propositional attitudes are tokenings of language-like mental symbols in the brain.) But it is also possible that the sententialist and causal-explanatory approaches will turn out to be in tension, with each one yielding some conclusions not sanctioned by, or perhaps even in conflict with, the other. Settling such a matter is perhaps the main burden of philosophical reflection on the nature of the propositional attitudes.

THE NATURE OF THE CONTENTS OF THE ATTITUDES

Common to both the sententialist and the causal-explanatory approaches to the propositional attitudes is the idea that the attitudes are *contentful* mental states. As mental states they are *about* things, typically objects and properties from the nonmental environment. Take Sanchez's belief that his grandmother smothers him with kisses. This belief is about his grandmother, him, and the property of smothering with kisses. This aspect of the propositional attitudes—their being *about* worldly states of affairs—raises a number of interesting and related philosophical issues. How does something (such as a mental state like Sanchez's belief) come to be about another thing (such as Sanchez's grandmother) in the first place? What *determines* what a mental state is about? How does the “aboutness” of mental states relate to other forms of “aboutness”? And finally, what can be said about cases in which a mental state is “about” something that does not really exist—unicorns, for example?

Philosophers have introduced the term “intentionality” to designate the domain of aboutness itself. In speaking of mental states as about the world, we are speaking of their *intentional* properties, just as in speaking of, for example, the sentence “Morty Morris has a big red wart on his nose” as about Morty Morris's big red nose wart, we are speaking of the sentence's intentional properties. Such properties are also called *semantic* properties: Both mental states and sentences—and arguably pictures, maps, models, and perhaps other things as well—have such properties. When something, such as a mental state or a sentence, has intentional or semantic properties, and so is about something, we can speak of what the state is about as *the content* of that state. Talk of the content of a mental state is to be understood in terms of what the mental state *represents* as the case. So Sanchez's belief has a content, which is what that belief represents to be the case: namely, that his grandmother smothers him with kisses.

It is noteworthy that a belief can represent something that is not the case. Suppose that Sanchez's grandmother does *not*, in fact, smother him with kisses (it's all “in his head,” so to speak). Then, supposing there is an inventory of all of the facts that make up our world, we would not find in this inventory any fact to the effect that Sanchez's grandmother smothers him with kisses. In short, there is no fact that is represented by his belief. But then what is this shadowy thing we are calling the content of his belief, that which his belief represents to be the case? Above we called this content a “proposition,” and we can now see

the attraction of the view that the content of an attitude is a proposition. For although it is hard to say exactly what propositions are, we can say at least this much: The existence of a given proposition does not depend on the existence of the corresponding fact that would make the proposition true. That is, there can be *false* propositions. Given that Sanchez's grandmother is not as Sanchez's belief depicts her, the proposition that is the content of Sanchez's belief is itself a false proposition.

The postulation of the proposition as the content of the attitudes raises a bundle of related metaphysical questions. What is the nature of propositions? (Is it essentially a linguistic entity? an abstract one? a mental one?) Do propositions have parts, and if so, what is the nature of those parts? Here we focus on a question bearing more directly on the philosophy of mind: How do propositional attitudes come to have the propositional content they have? More concretely, what makes Sanchez's belief a belief about his grandmother, and not, say, about ice cream sundaes or pink elephants or any of an infinite number of other things? Let us address this by asking which facts *fix* the content of his belief: Which facts are such that, if you fix them, then, no matter what else is going on in the universe, you have fixed the content of his belief that his grandmother smothers him with kisses? A natural first guess would be that the facts in question are facts regarding the mental image(s) in Sanchez's mind at the time that he calls this belief to mind. On such a view, once we fix the mental image(s) “in” his mind, we have fixed what his belief is about.

But this cannot be quite right. First, mental images do not appear to have the right sort of specificity to fix the content of the propositional attitudes. To see this, imagine a scenario in which Sanchez's grandmother has an identical twin, from whom the grandmother herself is indistinguishable, but whom Sanchez has never met or otherwise heard of. Then the image in Sanchez's mind “fits” his grandmother's twin as much as it “fits” his grandmother. But it seems implausible to think that his belief is about the twin, for he has never met or heard of her. Second, in addition to not having the right sort of specificity, mental images are too unstable and subjective to fix the contents of one's attitudes. This is clearest in cases in which the subject matter of the attitude is an abstract one. Precisely what image goes before your mind when you call forth your belief that $1+1=2$? And what image is before your mind when you believe that space is (or is not) infinite? Will it be true that any two people who believe e.g. that $1+1=2$ will have the same type of image before their minds? Presumably not. But then how

does the image fix the content of their belief? It seems that what they have in common, in virtue of which they both count as believing that $1+1=2$, is something other than a particular type of image.

And the same point can be made even in cases in which the subject matter of the attitude is not abstract. Take Roger's belief that Morty Morris has a big red wart on his nose. Since Morty Morris is Roger's best friend, Roger has a vivid mental image of Morty (wart and all). But Mathilde, who (having been told by Roger) also believes that Morty Morris has a big red wart on his nose, has never met Morty, and therefore has no such image. Again it seems that what Roger and Mathilde have in common, in virtue of which they both count as believing that Morty Morris has a big red wart on his nose, is something other than a particular type of mental image in mind.

These arguments (and the examples on which they are based) raise a host of issues regarding how propositional attitudes come to have the propositional content they have. Consider first the relation between such contents and the environment in which one lives and interacts. One plausible account of why Sanchez's belief is about his grandmother, rather than her identical twin, is that his belief was caused and sustained by activities involving one woman and not the other. So it can seem that interaction with one's environment is relevant to the determination of the contents of one's attitudes. Next consider the relationship between language and the content of the attitudes. Recalling that mental images are too unstable and subjective to fix the contents of attitudes, we might ask: Precisely what do Roger and Mathilde have in common, in virtue of which they both count as believing that Morty Morris has a big red wart on his nose? At least part (but only part!) of the answer is that they are both disposed to accept and assert a sentence that *means* that Morty Morris has a big red wart on his nose. Perhaps, then, among the facts that fix the content of one's attitudes we must include facts regarding the meanings of one's words.

These conclusions highlight one of the bigger controversies in the theory of content. In particular, we have seen at least three types of fact that might be regarded as relevant to fixing the content of one's attitudes. We started off with the suggestion that facts regarding the subject's mental images fix the content of her attitudes, but we moved quickly to include facts regarding causal history and then on to facts regarding the meanings of one's words. These correspond roughly to three distinct

theoretical options available with respect to the sort of facts needed to fix the content of one's attitudes.

Content internalism is the view that the only facts needed to fix the content of a subject's attitudes are facts that do not presuppose the existence of anything beyond the subject herself. The view with which we started, according to which the facts regarding the subject's mental images fix the contents of her attitudes, is one version of content internalism. But the content internalist can allow other sorts of facts, so long as these do not presuppose the existence of anything beyond the subject herself; and the most plausible versions of content internalism (for which see Searle 1983) include facts about the individual's use of language, where the meanings of her words are not thought to depend on the existence of anything beyond the subject herself. Of the various arguments for content internalism, one of the most influential is what we might call the argument from "intentional inexistence." Consider, to begin, that one can form a belief which is "about" something that does not exist—as with Ponce de Leon's belief that the Fountain of Youth is in Florida, or Roger's belief that the largest natural number is even. What is more, it would seem possible (though of course highly unlikely) that none of our beliefs succeed in being about any existing thing: Perhaps you are suffering an eternal and systematic hallucination in a world containing nothing but your own mind! But in that case, although your beliefs remain the same (or so it might seem), there are no worldly objects for them to be "about." This suggests that the "aboutness" properties of beliefs should be understood in such a way as not to presuppose the existence of anything beyond the thinking subject.

Many philosophers, unconvinced by this sort of argument, have thought that the internalist view is too restrictive in the set of facts it regards as relevant to fixing the content of the attitudes. A second view, *content individualism*, expands the set of content-fixing facts to include not just the facts allowed by the content internalist, but also any facts regarding the thinker's own causal history. (See Davidson 1984 and 2001 for an example of a view that combines *content externalism*, which is the denial of content internalism, with content individualism.) Although the cost of moving from internalism to individualism is that of having to rebut the argument from intentional inexistence—something that forces the individualist to come up with an account of beliefs "about" non-existent "objects"—the payoff of making this move can be made clear in connection with the following development of Sanchez's case. Sanchez

has an identical twin, Twin-Sanchez, separated from Sanchez from birth. Twin-Sanchez has interacted only with twin-granny, the identical twin of Sanchez's grandmother. Further, the course of experience Sanchez has with his grandmother is internally indistinguishable from the course of experience Twin-Sanchez has with twin-granny. So, for example, at the very moment Sanchez sees his grandmother wearing a lovely purple vest and making waving motions as she smiles, Twin-Sanchez sees twin-granny wearing an indistinguishable lovely purple vest making waving motions as *she* smiles; at the very moment Sanchez hears his grandmother singing a lovely melody, Twin-Sanchez hears twin-granny singing an indistinguishable lovely melody; and so forth through time. At one point each of the Sanchez twins, admiring the grandmother in his presence, forms a belief he would express with, "She has a wonderful voice." The natural view is that the contents of their beliefs differ: Sanchez's belief represents *his* grandmother (not twin-granny) as having a wonderful voice, whereas twin-Sanchez's belief represents twin-granny (not granny) as having a wonderful voice.

The content individualist can easily accommodate this natural view, as the difference in content can be fixed by the facts regarding each twins' causal history (with distinct grannies). The content internalist, by contrast, will have trouble accepting the natural view: Since the twins' course of experiences are internalistically indistinguishable, there will be some pressure on the content internalist to treat the twins as having beliefs *with the very same content*. (See Searle 1983 for an attempt by an internalist to avoid this conclusion.)

But if the content individualist has this virtue over the internalist, some philosophers have felt that individualism does not go far enough. A third position, which we might designate as *content anti-individualism*, is still more liberal in the range of facts it regards as relevant to fixing the content of a subject's attitudes. As its name suggests, content anti-individualism is the denial of content individualism. But it is helpful to see why a theorist might deny that "individualistic" facts suffice to fix the content of a subject's attitudes. The controversy has to do with the role of language in fixing the content of the attitudes. In one sense, it is uncontroversial that the meaning of one's words determines the contents of the attitudes one expresses with those words. The controversial matter regards what determines the meaning of one's words. The individualist maintains that no facts beyond those regarding the individual speaker herself—the conditions under which she uses her words, how she herself expli-

cates their meanings—are needed to fix the meaning of her words; whereas the anti-individualist maintains that these "individualistic" facts do not suffice to fix the meanings of her words. The insight (or alleged insight) behind anti-individualism is that individual language users typically defer to, and take themselves to be answerable to, public standards of correct usage. Such standards are not typically fixed by the individual's *own* word usage or meaning-explications, but instead are fixed by the usage of other speakers (Kripke 1972) and the meaning-explicating practices of the relevant experts in her linguistic community (Putnam 1975 and Burge 1979).

Interestingly, the sententialist and causal-explanatory approaches to the attitudes bear on the debate regarding the nature of mental content. For example, among the reasons offered in defense of anti-individualism, Burge notes in "Individualism and the Mental" (1979) that variations in public standards for the correct use of a word lead to differences in *the belief-attributing sentences* that would be used to report a subject's beliefs. And among the reasons offered in defense of content internalism are considerations pertaining to the internal basis of mental causes (for which see Fodor 1980). Although neither argument is decisive, each suggests the core motivations for and potential liabilities of the various positions on mental content.

THE METAPHYSICS OF THE ATTITUDES: VERSIONS OF MATERIALISM

The question regarding the nature of mental content cannot be addressed in isolation from what we might call the metaphysics of the attitudes. What is the nature of the states and properties dubbed "the propositional attitudes"? How do such states and properties relate to the thinker's bodily states and properties? These questions, of course, force us to confront a particular version of the notorious mind-body problem.

The positions that can be taken on the relation between a subject's propositional attitudes and her bodily states and properties correspond to positions familiar from the general mind-body problem. *Attitude dualism* holds that propositional attitudes are *immaterial* states or properties of thinking subjects. But as with dualism generally, attitude dualism runs into trouble in connection with the causal role that the attitudes are thought to play: How do immaterial states or properties affect a subject's body? Most contemporary philosophers take some version of this problem to be decisive against dualism. And of these most go on to endorse *materialism*, according to

which all of the objects and properties of our world are material in nature. So we will restrict our discussion accordingly.

Among materialist views we can begin with the view known as *philosophical behaviorism*, according to which the so-called propositional attitudes really are nothing other than complex behavioral dispositions. Philosophical behaviorism itself (unlike psychological behaviorism) was originally motivated by the verification theory of meaning, according to which the meaning of a sentence consists in the conditions whose obtaining would *verify* the sentence (establish its truth). Since sentences such as “John believes that it’s raining” are typically regarded as true or false in virtue of observable behavior (e.g., John’s uttering “It’s raining!,” carrying an umbrella with him, putting on galoshes, and so forth), the result of applying the verification theory of meaning to attitude-ascribing sentences is that each such sentence is to be regarded as equivalent in meaning to a “behavioral translation,” a much longer sentence describing all of the behaviors and behavioral dispositions whose presence would verify the original sentence (see e.g. Ryle 1949). However, this view faces two obvious and devastating difficulties.

First, as noted in Putnam “Brains and Behavior” (1965), the view is either false or unacceptably circular. It is false if the translation of the target sentence (“John believes that it’s raining”) fails to capture all of the conditions whose presence would be taken as evidence for the truth of that sentence. But in order to avoid falsity on this score, the translation will need to make reference to other attitudes the subject has: For example, John’s uttering “It’s raining!” counts for the truth of “John believes that it is raining” only if he is speaking sincerely and believes that “It’s raining” means that it’s raining; John’s taking an umbrella with him (or putting galoshes on) counts for the truth of “John believes that it’s raining” only if he desires not to get wet and believes that the umbrella (galoshes) will prevent him from getting wet; and so forth. In fact, it would appear that the connection between attitudes and behavior invariably involves other attitudes in this way. But in that case, any attempt to translate a target attitude-ascribing sentence will yield a translation which itself contains mention of other attitudes. On pain of circularity, these latter attitude-ascribing components in the translation must also be translated. But then the problem begins again, and the whole approach appears doomed to an unacceptable sort of circularity.

Nor is this philosophical behaviorism’s only problem. A second objection is that philosophical behaviorism

surrenders the idea of propositional attitudes as *the causes* of behavior. Consider: that a sugar cube dissolves in water is the basis for regarding it as water-soluble; so it would be an empty explanation to regard its solubility in water as *the cause* of its dissolving on a particular occasion. (Compare the doctor spoofed in Molière’s play *La malade imaginaire*: He explained the sleep-producing character of a particular drug to its having a “dormative virtue.”) Similarly, if beliefs and desires are dispositions to act, then it would be an empty explanation indeed to regard beliefs and desires as *the causes* of action.

Given the failure of philosophical behaviorism, the desire to preserve the causal profile of the propositional attitudes within a materialist framework provided the main motivation behind *identity theory*. Recognizing the role of the attitudes as the causes of intelligent behavior, early identity theorists used the fact (or what they regarded as the fact) that the causes of intelligent behavior are to be found in the states and processes of the central nervous system, to conclude that the propositional attitudes are *identical* to those states and processes of the central nervous system. (For an early formulation of identity theory, albeit in connection with sensory rather than contentful states, see Smart 1962.) The proposed identity was between property-types: An “attitudinal” property-type (such as the property of *believing that it is raining*) was held to be identical to a property-type instantiated by the central nervous system (such as the property of *having such-and-such a pattern of neural activation in this-or-that region of the brain*). But this gave rise to an objection from the so-called multiple-realizability of mental states (Putnam 1967): On the assumption that creatures whose underlying neurophysiology is very different from our own might nevertheless be regarded as being the subjects of attitudes, such type-identity claims were much too strong.

Such an objection to type-identity theory acquired additional force in light of the development of sophisticated forms of artificial intelligence. Alan Turing’s famous “Turing Test” (1950) taught that a system was to be regarded as “intelligent” so long as it behaved in a way that would lead those with whom it interacted to regard it as intelligent. The implicit idea was that any system with the right sort of *functional complexity*—as seen in its capacity to acquire and process information from its environment and to use this information to guide its subsequent actions—was to be regarded as intelligent (and hence, given some plausible assumptions, as a subject of the propositional attitudes). The result was what is perhaps the most widely accepted view of the metaphysics of

the attitudes: *functionalism*. According to the functionalist, propositional attitudes are best characterized by their functional or causal profile. So just as it would be a mistake to identify the property of *being a carburetor* with the property of *being made of metal and shaped in such-and-such a way*—surely being a carburetor is more a matter of function rather than material—so too it would be a mistake to identify the property of *believing that it is raining* with some particular property of the body. Rather, a subject has this property, and so counts as believing that it is raining, when the subject is in a state with a certain functional or causal profile—one that is caused in certain characteristic sorts of ways (e.g., seeing rain) and interacts with other functionally defined states to bring about certain effects (e.g., producing utterances of “It’s raining!,” movements to retrieve the umbrella when leaving, and so forth).

According to the functionalist, the first task in connection with the metaphysics of the attitudes is to specify the functional role corresponding to each distinct attitude. Once that task is completed, the functionalist philosopher can then pass on to empirical investigation the task of identifying what particular physical property *realizes* that functional role in a given system. (Compare: Once the functional role of a carburetor has been specified, we can go on and ask which feature of a particular car realizes that role.) Such a view is often advanced as part of a “computational” theory of the attitudes, according to which the functional role of particular mental states is best understood in information-processing terms. So formulated, functionalism, as shown by A. Newell (1980) and David Marr (1982), has been popular not only in the philosophy of mind but also in traditional cognitive science.

Of course, having specified what we take to be the functional role of a particular attitude-type (say, the belief that it is raining), there is no guarantee that there will *be* any state or property of the body or the central nervous system playing that role. Perhaps the very idea that there is a state playing that role is itself part of a mistaken theory of the mind, one whose fundamental postulates (beliefs, desires, and so forth) are as misguided as was the postulation of witches and other spiritual entities by misguided theorists of earlier ages. A number of philosophers, such as P. Churchland (1981), have begun to express such misgivings, arguing that the account of mind which postulates propositional attitudes is part of a “worm-eaten myth” that will be replaced as brain science progresses. Such a view, known as *eliminative materialism*, is perhaps the starkest version of materialism there

is, as it combines a general commitment to materialism with the view that there is nothing in the material world that answers to what we take the propositional attitudes to be. Though clearly radical, such a view has challenged mainstream theorists to further clarify what is at issue in the debate over the propositional attitudes.

PROPOSITIONAL KNOWLEDGE, DEFINITION OF

The traditional "definition of propositional knowledge," emerging from Plato's *Meno* and *Theaetetus*, proposes that such knowledge—knowledge that something is the case—has three essential components. These components are identified by the view that knowledge is justified true belief. Knowledge, according to the traditional definition, is belief of a special kind, belief that satisfies two necessary conditions: (1) the truth of what is believed and (2) the justification of what is believed. While offering various accounts of the belief condition, the truth condition, and the justification condition for knowledge, many philosophers have held that those three conditions are individually necessary and jointly sufficient for propositional knowledge.

The belief condition requires that one accept, in some manner, any proposition one genuinely knows. This condition thus relates one psychologically to what one knows. It precludes that one knows a proposition while failing to accept that proposition. Some contemporary philosophers reject the belief condition for knowledge, contending that it requires a kind of mentalistic representation absent from many cases of genuine knowledge. Some other contemporary philosophers endorse the belief condition but deny that it requires actual assent to a proposition. They propose that, given the belief condition, a knower need only be disposed to assent to a proposition. Still other philosophers hold that the kind of belief essential to propositional knowledge requires assent to a known proposition, even if the assent need not be current or ongoing. The traditional belief condition is neutral on the exact conditions for belief and for the objects of belief.

The truth condition requires that genuine propositional knowledge be factual, that it represent what is actually the case. This condition precludes, for example, that astronomers before Nicolas Copernicus knew that Earth is flat. Those astronomers may have believed—even justifiably believed—that Earth is flat, as neither belief nor

justifiable belief requires truth. Given the truth condition, however, propositional knowledge without truth is impossible. Some contemporary philosophers reject the truth condition for knowledge, but they are a small minority. Proponents of the truth condition fail to agree on the exact conditions for the kind of truth essential to knowledge. Competing approaches to truth include correspondence, coherence, semantic, and redundancy theories, where the latter theories individually admit of variations. The truth condition for knowledge, generally formulated, does not aim to offer an exact account of truth.

The justification condition for propositional knowledge guarantees that such knowledge is not simply true belief. A true belief may stem just from lucky guesswork; in that case it will not qualify as knowledge. Propositional knowledge requires that the satisfaction of its belief condition be suitably related to the satisfaction of its truth condition. In other words, a knower must have adequate indication that a belief qualifying as knowledge is actually true. This adequate indication, on a traditional view of justification suggested by Plato and Immanuel Kant, is suitable evidence indicating that a proposition is true. True beliefs qualifying as knowledge, on this traditional view, must be based on justifying evidence.

Contemporary philosophers acknowledge that justified contingent beliefs can be false; this is fallibilism about epistemic justification, the kind of justification appropriate to propositional knowledge. Given fallibilism, the truth condition for knowledge is not supplied by the justification condition; justification does not entail truth. Similarly, truth does not entail justification; one can lack evidence for a proposition that is true.

Proponents of the justification condition for knowledge do not share an account of the exact conditions for epistemic justification. Competing accounts include epistemic coherentism, which implies that the justification of any belief depends on that belief's coherence relations to other beliefs, and epistemic foundationalism, which implies that some beliefs are justified independently of any other beliefs. Recently, some philosophers have proposed that knowledge requires not evidence but reliable (or truth-conducive) belief formation and belief sustenance. This is reliabilism about the justification condition for knowledge. Whatever the exact conditions for epistemic justification are, proponents of the justification condition maintain that knowledge is not merely true belief.

Although philosophers have not agreed widely on what specifically the defining components of proposi-

tional knowledge are, there has been considerable agreement that knowledge requires, in general, justified true belief. Traditionally, many philosophers have assumed that justified true belief is sufficient as well as necessary for knowledge. This is a minority position now, owing mainly to Gettier counterexamples to this view. In 1963 Edmund Gettier challenged the view that if one has a justified true belief that p , then one knows that p . Gettier's counterexamples are:

- (I) Smith and Jones have applied for the same job. Smith is justified in believing that (i) Jones will get the job, and that (ii) Jones has ten coins in his pocket. On the basis of (i) and (ii), Smith infers, and thus is justified in believing, that (iii) the person who will get the job has ten coins in his pocket. As it turns out, Smith himself will actually get the job, and he also happens to have ten coins in his pocket. So, although Smith is justified in believing the true proposition (iii), Smith does not know (iii).
- (II) Smith is justified in believing the false proposition that (i) Jones owns a Ford. On the basis of (i), Smith infers, and thus is justified in believing, that (ii) either Jones owns a Ford or Brown is in Barcelona. As it turns out, Brown is in Barcelona, and so (ii) is true. So although Smith is justified in believing the true proposition (ii), Smith does not know (ii).

Gettier counterexamples are cases where one has a justified true belief that p but lacks knowledge that p . The Gettier problem is the difficulty of finding a modification of, or an alternative to, the traditional justified-true-belief analysis that avoids difficulties from Gettier counterexamples.

Contemporary philosophers have not reached a widely accepted solution to the Gettier problem. Many philosophers take the main lesson of Gettier counterexamples to be that propositional knowledge requires a fourth condition, beyond the justification, belief, and truth conditions. Some philosophers have claimed, in opposition, that Gettier counterexamples are defective because they rely on the false principle that false evidence can justify one's beliefs. There are, however, examples similar to Gettier's that do not rely on any such principle. Here is one such example inspired by Keith Lehrer and Richard Feldman:

- (III) Suppose that Smith knows the following proposition, m : Jones, whom Smith has always found to be reliable and whom Smith has no reason to dis-

trust now, has told Smith, his officemate, that p : He, Jones, owns a Ford. Suppose also that Jones has told Smith that p only because of a state of hypnosis Jones is in and that p is true only because, unknown to himself, Jones has won a Ford in a lottery since entering the state of hypnosis. Suppose further that Smith deduces from m its existential generalization, o : There is someone, whom Smith has always found to be reliable and whom Smith has no reason to distrust now, who has told Smith, his officemate, that he owns a Ford. Smith, then, knows that o , since he has correctly deduced o from m , which he also knows. Suppose, however, that on the basis of his knowledge that o , Smith believes that r : Someone in the office owns a Ford. Under these conditions, Smith has justified true belief that r , knows his evidence for r , but does not know that r .

Gettier counterexamples of this sort are especially difficult for attempts to analyze the concept of propositional knowledge.

One noteworthy fourth condition consists of a "defeasibility condition" requiring that the justification appropriate to knowledge be "undefeated" in that an appropriate subjunctive conditional concerning defeaters of justification be true of that justification. A simple defeasibility condition requires of our knowing that p that there be no true proposition, o , such that if q became justified for us, p would no longer be justified for us. If Smith genuinely knows that Laura removed books from the office, then Smith's coming to believe with justification that Laura's identical twin removed books from the office would not defeat the justification for Smith's belief regarding Laura herself. A different approach claims that propositional knowledge requires justified true belief sustained by the collective totality of actual truths. This approach requires a precise, rather complex account of when justification is defeated and restored.

The importance of the Gettier problem arises from the importance of a precise understanding of the nature, or the essential components, of propositional knowledge. A precise understanding of the nature of propositional knowledge, according to many philosophers, requires a Gettier-resistant account of knowledge.

PROPOSITIONS

On one use of the term, "propositions" are objects of assertion, what successful uses of declarative sentences say. As such, they determine truth-values and truth conditions. On a second, they are the objects of certain psychological states (such as belief and wonder) ascribed with verbs that take sentential complements (such as *believe* and *wonder*). On a third use, they are what are (or could be) named by the complements of such verbs. Many assume that propositions in one sense are propositions in the others.

After some decades of skepticism about the worth of positing propositions, the last quarter of the twentieth century saw renewed interest in and vigorous debate over their nature. This can be traced in good part to three fac-

tors: the development in intensional logic of formal models of propositions; (not altogether unrelated) attacks on broadly Fregean accounts of propositions; and a spate of work on the nature of belief and its ascription.

"Possible-worlds semantics" is a collection of methods for describing the semantical and logical properties of expressions such as *necessarily*; these methods developed out of work done by Saul Kripke, Richard Montague, and others in the 1960s. It illuminated the logic and semantics of modal terms such as *necessarily*, of conditionals and tenses, and other constructions as well. In such semantics one assigns a sentence a rule that determines a truth-value relative to various "circumstances of evaluation" (possible worlds, times, whatever); a sentence such as "it is necessary that S" has its truth-value determined by the rule so associated with S. The success of such accounts made it natural to hypothesize that propositions, qua what is named by expressions of the form "that S," could be identified with such rules—equivalently, with sets of circumstances such rules pick out.

Such a conception of proposition provides too crude an account of objects of belief or assertion: It implausibly makes all logically equivalent sentences express the same belief and say the same thing. A partial solution to this problem supposes that propositional identity is partially reflected in sentential structure, taking propositions themselves to be structured. Given the working hypothesis that a proposition's structure is that of sentences expressing it, critical to determining the proposition a sentence (use) expresses are the contributions made by sentence parts (on that use).

Gottlob Frege (1952) suggested that associated with names and other meaningful expressions are "ways of thinking" or *senses* of what the expressions pick out; one might suppose that sense and sentence structure jointly determine proposition expressed. Sense, in the case of names and other singular terms, has standardly been taken to be given by describing how one thinks of the referent. For example, the sense of "Aristotle" for me might be given by "the author of the *Metaphysics*"; if so, my uses of "Aristotle taught Alexander" and "the author of the *Metaphysics* taught Alexander" would, on a Fregean view, express the same proposition.

During the 1970s Kripke, David Kaplan, and others argued convincingly that this view is untenable: It is obvious, on reflection, that the truth conditions of the assertion or belief that Aristotle was *F* depend on Aristotle in a way in which the truth conditions of the assertion or belief that the author of the *Metaphysics* was *F* do not. So either ways of thinking are somehow tied to the objects

they present (so that the way I think of Aristotle could not present anything but Aristotle), or the contributions of expressions to propositions must be something other than senses.

The success of accounts of intensional language that ignored sense in favor of constructions from references, along with the apparent failure of Fregean accounts, led in the 1980s to debate over the merits of what is variously called direct-reference theory, Millianism, and (neo-)Russellianism, espoused at various times by a wide variety of theorists including Kaplan (1989), Mark Richard (1990), Nathan Salmon, and Scott Soames (1988). On such views sense is irrelevant to individuating a proposition; indeed, it is irrelevant to semantics. In particular, what a name contributes to a proposition is its referent: The proposition that Twain is dead is the same singular proposition as the proposition that Clemens is.

Neo-Russellians identify the object of assertion and the referent of a “that” clause with a Russellian proposition. They allow that there is such a thing as a “way of grasping” a proposition and that belief in a singular proposition is mediated by such. Against the intuition that, for example, A: Mo believes that Twain is dead, and B: Mo believes that Clemens is dead, might differ in truth-value, direct-reference accounts typically suggest that a pragmatic explanation is appropriate. Just as an ironic use of a sentence can convey a claim without literally expressing it, so a sentence about Mo’s beliefs might convey information about Mo’s way of grasping a singular proposition, without that information being part of what the sentence literally says. If this is so, intuitions about A and B are explained pragmatically.

Those unhappy with this account of propositions have looked elsewhere. Many accounts of propositions identify the proposition determined by S with some construction from linguistic items associated with S and the semantic values of S’s parts. James Higginbotham has identified the referents of “that” clauses with phrase markers that may be annotated with referents; Richard has suggested that the referent of a “that” clause be identified with something like the singular proposition it determines paired off with the sentence itself. In making linguistic items constitutive of propositions, these views run counter to ones, like Frege’s and Bertrand Russell’s, that closely tie meaning and synonymy to propositional determination. On linguistic views of propositions the synonymy of *groundhog* and *woodchuck* does not assure the identity of the proposition that groundhogs are pests with the proposition that woodchucks are. Other theo-

rists (Gareth Evans, for example) have attempted to revive a version of Frege’s views of propositions.

Many philosophers continue to doubt the utility of positing propositions. Quineans argue that meaning and reference must be determined by behaviorally manifest facts but that such facts woefully underdetermine assignments of meaning and reference; they conclude that there is nothing about language that need or could be explained by positing propositions. Stephen Schiffer has argued that propositions are a sort of “linguistic posit”: that we accept nominalizations of the form “that S” as referring to singular terms and have coherent criteria for using sentences in which those terms occur is itself sufficient for its being true that there are propositions. Such a deflationist view implies neither the possibility of a substantive account of propositions (on which, for example, the proposition expressed by a sentence is compositionally determined), nor that propositions play a substantive role in explaining semantic phenomena.

PROPOSITIONS [ADDENDUM]

Despite the rearguard efforts of Robert Stalnaker and Max Cresswell, by the late 1990s it became widely acknowledged that sets of possible worlds are too coarse-grained to serve as propositions. It is safe to say that among those philosophers who believe in propositions, most think of them as sententially structured entities, composed out of the contents of the words and phrases in the sentences that express them. Fregeans hold that these contents are Fregean senses; Russellians hold that they are objects, properties, and relations.

Yet the 1990s also saw new challenges and approaches to structured propositions. George Bealer and Michael Jubien have independently argued (i) that it is counterintuitive to hold that we believe and assert structured complexes, and (ii) that theories of structured propositions are subject to the same problem that Paul Benacerraf raised for set-theoretic reductions of arithmetic. On one such reduction, the number 2 is identified with the set $\{\{\emptyset\}\}$; on another, 2 is identified with $\{\emptyset, \{\emptyset\}\}$, where \emptyset is the null set. Benacerraf's problem is that there are no principled reasons for preferring one or the other reduction, or any of the infinitely many equally good alternatives, and so none of these reductions can be correct. For similar reasons, the proposition that Jones loves Smith cannot be identified with the ordered set $\langle \text{love}, \langle \text{Jones}, \text{Smith} \rangle \rangle$, or with $\langle \text{Jones}, \langle \text{love}, \text{Smith} \rangle \rangle$, or

These and other problems led Bealer to reject all reductions of propositions to structured objects and to hold that propositions are unstructured and irreducible. They led Jubien to reject propositions altogether in favor of a Russellian multiple-relation theory of judgment, which dispenses with propositions by analyzing "believes" and other attitude verbs as many-place predicates that relate subjects to objects, properties, and relations instead of to whole propositions. However, (i) is debatable, and (ii) can be avoided if one can provide a rationale for preferring one system of reduction. For example, Jeffrey King holds (roughly) that a structured proposition is obtained by replacing the words of a sentence with their contents while retaining the syntactic relations in the logical form of the sentence. This solves Benacerraf's problem because the structure in propositions is identified with the syntactic structure in the logical form. The connection with syntax provides a principled reason for identifying propositions with the structured objects proposed by King.

Another approach to structured propositions is due to Jon Barwise and John Etchemendy, who use what they call "Austinian propositions," named after the Oxford philosopher J. L. Austin, in their solution to the liar paradox. An Austinian proposition is like a structured Russellian proposition except that it contains a contextually determined situation that the proposition is about. So while the Russellian proposition that Claire is playing cards is true just in case Claire is playing cards, the Austinian proposition that Claire is playing cards is true just in case Claire is playing cards in the contextually determined situation. For every situation s , there is a liar proposition f about s that claims that f is false in s . In Barwise and Etchemendy's formal development, it turns out that every such f is simply false. However, for every s , there is an expanded situation s' , and there is a true proposition p about s' that claims that f is false in s' . The intuition that the liar proposition f is both true and false arises out of a failure to keep separate the distinct Austinian propositions f and p .

A general challenge to propositions has come from Donald Davidson, who has used the so-called slingshot argument to collapse all facts into a single Great Fact, effectively robbing facts of their philosophical utility. Davidson argues that if we give up on facts, we should also give up on entities that represent facts, such as propositions. The slingshot argument can also be used directly against propositions to show that all true propositions collapse into a single Great Proposition. But as Stephen Neale has shown, the slingshot argument can be avoided as long as one holds that sentential operators like "the fact that ... is identical to the fact that ..." and "the proposition that ... is identical to the proposition that ..." satisfy certain logical constraints on inference rules involving definite descriptions. This constraint can easily be satisfied if one adopts a Russellian analysis of definite descriptions (which construes "The f is g " as "There is exactly one f , and it is g ").

PROTAGORAS OF ABDERA

Protagoras of Abdera in Thrace, most famous of the Sophists, was born not later than 490 BCE and probably died soon after 421 BCE. According to Plato, he was the first to declare himself a professional Sophist. He went from city to city in the Greek world, offering instruction in return for money, and he undertook above all to train young men in the art of politics. He was well known in Athens, where he enjoyed the friendship of Pericles—he produced a theoretical basis for Periclean democracy and was asked by Pericles to draft the constitution for the new colony of Thurii in 443 BCE. He made contributions to grammatical and rhetorical theory, and his views on religion provoked charges of impiety against him in the courts, which led to his exile from Athens at the end of his life and to the public burning of at least one of his books.

His writings were numerous and included "On Truth," "On the Gods," and "Antilogic" (or "Antilogies"). Later writers probably took their information about him mainly from the accounts of Plato, Aristotle, and Sextus Empiricus, but one of his works was read by Porphyry in the third century CE, and in the Hellenistic period he was regarded as sufficiently important for his statue to be set up, together with those of Plato, Aristotle, and other thinkers, in the Serapeum at Memphis in Egypt.

Since the time of Plato, Protagoras's main doctrines have been regarded as possessing considerable philosophical interest, even by those who deny philosophical importance to the Sophists in general; but very divergent interpretations have been propounded. With no surviving works and virtually no fragments, interpretation must depend upon the assessment of the evidence of Plato, Aristotle, and Sextus Empiricus. In what follows, the view is taken that Plato in the *Theaetetus* correctly states the basic position of Protagoras and then proceeds to distinguish certain possible developments of this position not held by Protagoras. The basic position was independently understood in the same way by both Aristotle and Sextus Empiricus, each of whose information was

not simply derived from the *Theaetetus*. This would be denied by some scholars.

EPISTEMOLOGY

The starting point must be the famous contention that "man is the measure of all things, of things that are that [or 'how'] they are and of things that are not that [or 'how'] they are not." Theodor Gomperz maintained that "man" is to be understood collectively in the sense of "mankind as a whole" or "the human race." But against this, the evidence of the *Theaetetus* 152A–B seems to show conclusively that it is individual men that Protagoras had in mind in the first instance, although, as will be seen, his theory is capable of easy extension to groups of men, and he probably made this extension himself.

According to Plato's example in the *Theaetetus*, when the same wind appears cold to one person and warm to another person, then the wind is warm to the person to whom it appears warm and is cold to the person to whom it seems cold. It follows that all perceptions are true and the ordinary view is mistaken, according to which, in cases of conflict, one person is right and the other person is wrong about the quality of the wind or of anything else. This clearly was the position held by Protagoras, but it is not clear exactly how he came to this view. It is often held that his position is a kind of subjective idealism similar to that of Bishop Berkeley, according to which qualities in a thing are for the person to whom they seem, so long as they seem to him, but have no existence independent of their seeming.

Against this view, Sextus Empiricus is explicit: All qualities perceived by different persons are actually present in matter. Sextus's introduction of matter may well be anachronistic, but his account suggests an alternative view, accepted by F. M. Cornford among others, according to which opposite qualities are copresent in objects, and in cases of conflict of perceptions between two persons, what happens is that we have a sort of selective perception—one person perceives one quality and the other its opposite, both qualities being present in the situation, waiting to be perceived, as it were, independently of any actual perceiving by a subject. This view seems to have the support of Aristotle, who always treats Protagoras's doctrine as involving the denial of the principle of contradiction, and the view coincides with incidental pointers in Plato's account ("the same wind"—152B; "perception, then, is always of something that is"—152C). It is true that in the "secret doctrine" attributed to Protagoras by Plato (152Cff.) the independent status of sense objects is undermined, but the fact that this is presented as a secret

doctrine is surely conclusive evidence that it was a doctrine not publicly associated with Protagoras.

The “man-measure” doctrine is presented by Plato in the first instance as a doctrine about perception of sensible qualities. But it is clear that Plato supposed that for Protagoras it also applied to moral and aesthetic qualities such as “just” and “beautiful.” It is especially in these cases that the extension of the doctrine to groups of people was made by Protagoras—“whatever seems just to a city is just for that city so long as it seems so.” Probably Protagoras did not extend his doctrine to apply to all judgments; this was done immediately by his opponents in the famous *peritrope*, or “turning of the tables”: Let us suppose that whatever seems true to any person is true for the person to whom it seems so. If this is the doctrine of Protagoras, then Protagoras will hold that those who hold that Protagoras’s theory is false are holding the truth (*Theaetetus* 171A). But Plato points out that if Protagoras could pop his head up through the ground, he would surely have an answer to this objection.

At the very least, Protagoras was clear about one point. In the case of conflict about perceived qualities all perceptions are true. But some perceptions are better than others, for example, the perceptions normally found in a healthy man as distinct from those found in a man who is ill. It is the function of a doctor, Protagoras held, to change a man who is ill so that his perceptions become those of a man who is well. Likewise, in moral, political, and aesthetic conflicts it is the function of the Sophist as a teacher to work a change so that better views about what is “just” and “beautiful” will seem true to the “patient”—better, that is, than those that previously seemed true to him. All the “patient’s” views are equally true, but some are better than others.

There is nothing to suggest that by “better” Protagoras meant what will seem better. Quite the contrary. Better views are views that have better consequences, and consequences which are better are so as a matter of fact, independently of whether a person thinks them better or not. In other words, Protagoras here made an exception to his man-measure doctrine. There is every reason to suppose that he would have excepted the class of judgments about the consequences of judgments from his principle. Indeed, there is no actual evidence in any ancient author that Protagoras himself ever applied his doctrine to statements other than those about perceived qualities and moral and aesthetic qualities treated on the same plane as visually perceived qualities. What probably happened was that he propounded his doctrine in certain general statements such as “whatever seems to anyone is

so for that person,” without adding the qualifications that he really intended; thus he gave a handle to his enemies, which enabled them to apply the *peritrope* and similar objections.

The above account rests primarily upon Plato’s *Theaetetus*. To it may be added evidence from other sources. According to Diogenes Laërtius, Protagoras was the first to propound the theory that there are two *logoi*, or accounts, to be given about everything. This has sometimes been treated as simply the now familiar rhetorical doctrine that “there are two sides to every question.” But this theory was used as a method of argument, and it should probably be related to the man-measure doctrine and to what Plato called “Antilogic,” the probable title of one of Protagoras’s treatises. In conflicts about perceived qualities, and also moral and aesthetic qualities, there might seem room for an infinite variety of “seemings,” but if we take any one as a starting point, for instance, that the wind seems warm, all other seemings may be expressed as the negative of this, namely “not-warm.” This was clearly the way in which Plato tended to regard phenomena—as did the antilogicians, too—namely, as always being both “warm” and “not-warm.” In this view, Plato was probably following Protagoras. It is possible that Protagoras associated with the two-*logoi* principle the prescription attributed to him by Aristotle “to make the lesser [or ‘the weaker’] argument the stronger.” This may have been what the Sophist was expected to do when altering a man’s opinions for the better.

SOCIAL THEORY

In Plato’s dialogue *Protagoras* we are given a coordinated theory of the Sophist in relation to society and of a possible theoretical basis for a Periclean-style democracy. All is completely consistent with the positions attributed to Protagoras in the *Theaetetus*. When Protagoras professes to make men good citizens, Socrates objects that while the Athenians call in experts to advise on technical matters, they regard all citizens as capable of advising them on matters relating to the city. This seems to imply that Athenian democracy leaves no place for expert instruction in citizenship. Protagoras replies with a myth followed by a nonmythical exposition that while all men share in the qualities that make good citizens, they do not do so by nature but acquire these qualities by instruction and by practice. These qualities are beliefs and opinions about what is just and right. In a sense, the whole community teaches its members about these matters, and so all are rightly consulted about political matters. But the expert teacher, such as the Sophist Protagoras, can

improve opinions on such matters, whether it be in the case of an individual or in the case of a whole community.

OTHER VIEWS

Protagoras's doctrines ranged beyond the topics discussed above to cover physical and mathematical problems as well, but it is no longer possible to state his actual teachings on these problems. He seems to have held that a tangent touches a circle not only at one point, but at more than one, clearly arguing from visual experience of drawn lines. Parmenides had rejected the world of seeming in favor of his world of being; Protagoras took the opposite path and attempted to expound a world in which all appearances were true and where there was nothing outside or beyond what appeared. This involved the copresence of opposed and contradictory qualities at many points. Protagoras was prepared to accept and explain this copresence through his "man-measure" principle, either on the basis of a theory of subjective idealism or, more probably, on the basis of a conception of a phenomenal world actually composed of opposites (a conception typical of the pre-Socratics). This conception seemed to Plato to be substantially correct for the phenomenal world, hence his great interest in Protagoras. But Plato felt that this view made it impossible to give any account or explanation of phenomena, and to be able to give an explanation seemed to him essential.

Diogenes Laërtius says that for Protagoras the soul is nothing apart from its perceptions. This suggests a phenomenalistic view of the soul as well as of everything else. Diogenes' account may be correct, although doubts have been cast upon it. If it is correct, however, it probably was not intended to imply any doctrine like the modern theory of neutral monism, but simply to deny the existence of any "submerged," or nonphenomenal, element in the soul.

PROUDHON, PIERRE-JOSEPH

(1809–1865)

Pierre-Joseph Proudhon has been called the father of anarchism, a title that is accurate insofar as organized anarchist movements throughout the world can be traced to his teachings and to the actions of his disciples. Proudhon was also the first writer deliberately to accept the title of anarchist, which he did in 1840. Before his time the term had been used to denote one who seeks to promote social disorder; Proudhon argued that it could be used with more justice to describe one who seeks social order without authoritarian government. "As man seeks justice in equality, so society seeks order in anarchy," he said. "Anarchy—the absence of a master, of a sovereign—such is the form of government to which we are every day approximating." Such doctrines were not entirely original; the English writer William Godwin had expounded them fifty years earlier without describing them as "anar-

chist,” but Proudhon appears to have been uninfluenced by Godwin and to have reached his conclusions independently.

Proudhon prided himself on being a man of the people. He was born in Besançon, capital of Franche-Comté, of Jura peasant stock. His childhood was hard, and after a brief period at the college in Besançon, he received his education largely through his work as a printer; he taught himself Greek and Hebrew and developed a prose style that eventually won the admiration of Charles-Pierre Baudelaire, Gustave Flaubert, and Victor Hugo. The turning point in Proudhon’s career came when he was awarded a scholarship by the Besançon Academy in 1838. This took him to Paris and gave him the leisure to formulate his ideas and to write his first important book, *Qu’est-ce que la propriété?* (*What Is Property?*, Paris, 1840). This book, hailed by Karl Marx as “the first decisive, vigorous and scientific examination” of the institution of property, gained notoriety because in one passage Proudhon defined property as “theft.” The author’s love of telling phrases distorted the nature of his argument, for *Qu’est-ce que la propriété?* was in fact an investigation of abuses that had entered into the institution of property rather than a condemnation of property itself. The arguments that Proudhon put forward in this early book, on the nature of property and the faults of government, are those which he elaborated and gave a deeper philosophical backing in his later works.

Proudhon attacked the existence of private property that allows the exploitation of the labor of others, such as the owning of land by those who do not work it; he had only approval for the “possession” that allows a worker to dispose of what his hands make. “The right to products is exclusive—*jus in re*; the right to means is common—*jus ad rem*.” This is so because the means of production, the heritage of techniques and inventions, have been built up by human cooperation, and no man has a right to use them exclusively for his own benefit. However, for the sake of independence, Proudhon granted the need for each man to control the land or tools he can use. In this early book he still thought in terms of a peasant-and-handcraft society.

Proudhon attacked unreformed property because it negates equality, but he rejected the communist theories of his time (principally those of the French utopian socialists) because they denied independence. Here Proudhon came to the political aspect of his argument—both unreformed property and communism are dependent on forms of authority to maintain themselves. But how far is authority justified? Proudhon contended that it

arises from the tendency of social animals and primitive man to seek leaders. As reason develops, criticism, protest, and rebellion arise. Emergent political science finds the laws by which society functions in the nature of things, not in the whims of rulers. At this point anarchy, administration without government, becomes possible. Proudhon, at this stage under the influence of Hegelian ideas imperfectly absorbed from French reviews, created a triad. The thesis is property, which destroys equality; the antithesis is communism, which denies independence; the synthesis is anarchy or liberty, which is embodied in a society of producers bound together by a network of free contracts. In the widening recognition of mutual interests, government becomes unnecessary.

During the 1840s Proudhon served for several years as office manager for a water transport firm in Lyons, work that allowed him to travel frequently to Paris. In these two settings his theory of mutualism—the form of anarchism particularly associated with him—developed. Political radicalism flourished in mid-nineteenth-century Lyons, and Proudhon encountered there the disciples of Étienne Cabet, Charles Fourier, Pierre Leroux, and other socialist prophets. He developed the idea of a worldwide working-class organization on an economic basis rather than a political one. This led him to place faith in various forms of mutual credit systems that might eventually make governmental administration unnecessary; he envisaged such associations as becoming worldwide. In Paris, Proudhon associated with some of the leading European revolutionary theorists, including Marx, Mikhail Bakunin, and Alexander Ivanovich Herzen. However, his personal and theoretical incompatibility with Marx soon became evident; the historic conflict between libertarian and authoritarian views of socialism began with the split between Marx and Proudhon, which dates from Marx’s attack in *La misère de la philosophie* (Paris, 1847) on Proudhon’s *Système des contradictions économiques* (2 vols., Paris, 1846). Bakunin and Herzen, on the other hand, eventually became Proudhon’s most important disciples.

During the 1840s Proudhon, an eclectic thinker, took what he found valid from the writings of G. W. F. Hegel, Ludwig Feuerbach, Immanuel Kant, and other German philosophers, as well as from Auguste Comte and the French utopians. He evolved a philosophy that left out the third term of the Hegelian triad, and accepted contradiction as an enduring force tending toward a dynamic equilibrium—the desirable condition of existence. He denied all absolutes, all utopian aspirations to permanent solutions, and, in his *Philosophie du progrès* (Paris, 1853) saw

progress as “the affirmation of universal movement and in consequence the negation of all immutable forms and formulae, of all doctrines of eternity, permanence, or impeccability, and of every subject, or object, spiritual or transcendental, that does not change.” He was, deliberately and avowedly, an antisystematic philosopher.

Proudhon assumed the standpoint of a critical independent, and as such he became the most outspoken journalist of the period, giving qualified support to the French revolution of 1848. His *Le représentant du peuple* (1848) was the first anarchist newspaper published with any regularity; harried by suppressions and fines, it survived under various names for more than two years. Proudhon was elected in June 1848 to the Constituent Assembly, where he maintained an intransigent minority position. He also planned a people’s bank, based on his mutualist ideas, which never materialized because he was imprisoned for attacks in his paper on Louis Napoleon, then president of the Republic.

Proudhon’s three years of imprisonment were light: He was allowed occasional days out on parole, on one of which he married Euphrasie Piégard, and he wrote two of his most important books, *Les confessions d’un révolutionnaire* (Paris, 1850), an analysis of the events of 1848 that states the aim of anarchist revolutionism as “no more government of man by man, by means of the accumulation of capital,” and *Idée générale de la révolution au XIX^e siècle* (*General Idea of the Revolution in the Nineteenth Century*, Paris, 1851). The latter book comes nearer than anything else Proudhon wrote to presenting his view of the ideal libertarian society, based on contract instead of laws, with authority decentralized in communes and industrial associations, with frontiers abolished and flexible federation replacing the centralized national state.

During the early years of the Second Empire, Proudhon was subjected to constant police persecution, and in 1858 he was again sentenced to three years’ imprisonment for an offense against the press laws. He fled to Belgium, where, although pardoned in 1860, he lived until 1862. During his final years in Paris, he gained a considerable mutualist following among French workingmen, and before he died early in 1865, he learned that his followers had taken a leading part in the meetings that led to the founding of the International Workingmen’s Association.

During his final years Proudhon wrote a number of books that elaborated important aspects of his doctrines. *Du Principe fédératif* (Paris, 1863) summarized his criticism of nationalism and developed his ideas of communal organization leading gradually to world federation.

De la Justice dans la révolution et dans l’église (3 vols., Paris, 1858) opposed his own theory of an immanent justice to transcendentalist ideas of justice. *De la Capacité politique des classes ouvrières* (published posthumously in Paris, 1865) developed Proudhon’s view of the power of the working class to achieve its own liberation by economic means.

Later anarchism and syndicalism were largely influenced by Proudhon’s doctrines, as was the populist movement in Russia. As the Russian anarchist Mikhail Bakunin said, “Proudhon was the master of us all.”

PROUST, MARCEL

(1871–1922)

The French author Marcel Proust was born and educated in Paris. He lived there all his life, leaving only for short holidays or artistic pilgrimages, most of which were to the great cathedral cities of France. His father, a professor of medicine, was Catholic; his mother, whom he adored, was Jewish. Both traditions, as well as his consuming interest in French history and culture, played important roles in his life and art, although he was neither religiously orthodox nor politically chauvinistic. He undertook a considerable and seemingly futile search for a vocation and did some writing, most of which was discarded drafts of his future novel. Suffering terribly from asthma and from certain guilts about his homosexuality, but with economic as well as spiritual means sufficient to indulge and transmute these ills, Proust ensconced himself in his famous cork-lined room to write his masterpiece, *A la recherche du temps perdu*.

PHILOSOPHICAL THEMES

Although Proust compared a work of art in which there are theories to an object on which the price is marked, *A la recherche* is, nonetheless, a philosophical novel. There are two major philosophical themes woven into the novel: that reality is composed of artistic essences and that the search for essences ends in their dissolution. Proust stated only the first theme; the second, however, is implied by much of the action of the novel.

In the last volume of the novel, *Le temps retrouvé*, Proust, as narrator and participant, stated his theory of artistic essences as reality; this theory, because of its role in the context of the whole novel, must be understood as an integral part of it, along with the characterization, dialogue, and plot. According to Proust's theory, we live in a world of people, places, and things, all of which are organized spatially or temporally, in the ordinary sense of space and time, and which impinge on us. Most of us merely react to these phenomena. The true artist, however, like the scientists, attempts to find the laws that govern these phenomena. Whereas the scientist proceeds by his intellect, the artist cannot, for his laws are to be discovered only by intuition. The artist's intellect supple-

ments, but it cannot supplant, intuition. Intuition is that state of mind in which the artist—rooted in past experiences, nourished by suffering, and graced by an involuntary memory of a past sensation joined with a similar present one—extracts the qualitative similarity or essence from these sensations in order to embody that essence in a metaphor which, like the essence, is not subject to the ravages of time. Thus, these essences are the only true reality, and their artistic expression the only true judgment on reality.

Proust, it is important to realize, did not deny the existence of temporal or spatial relations, but he rejected them as unreal. Hence, he must understand by *reality* something quite distinct from *existence*: *reality* for him functioned as an honorific term denoting that which is salvageable from the past and which transcends the present—that, therefore, which is ultimate in the precise sense of being out of time. *Reality*, in effect, denotes the essences extracted by intuition from what exists in relation to what existed.

It has been claimed that Proust's conceptions of time and intuition are Bergsonian. It seems, however, that there are important differences. According to Henri Bergson, time is essentially duration (*durée*). The concepts of the past, present, and future cannot apply to time because they spatialize it. Duration can only be experienced, not thought of or talked about; it is the indivisible, ultimate fact of process in the world, and intuition is the experience of duration, a direct acquaintance with it. For Proust, however, time is not duration; it consists of chronological relations among events. Nor is time ultimate; only the timeless essences are that. Finally, intuition for Proust is an extraction from, not an immersion in, time.

Nor is Proust's theory Platonic, as has sometimes been suggested. Plato's timeless essences are perfect and have their being absolutely independently of the spatial and temporal particulars of this world; the Proustian essences are at most more or less imperfect copies of the truly real forms.

Besides this aesthetic-ontological theme, which Proust integrated magnificently in the novel, there is the nether theme of the dissolution of essences in the very search for them. Although he never stated this theme, much of the novel embodies it. The treatment of love is probably the best single example. Through the narration of many different love relationships, commonly regarded as a major achievement of the novel, Proust dramatized that love has no essence, only an inexhaustible set of properties, none of which is necessary or sufficient. Here

intellect supplants rather than supplements intuition. Proust's observations, analyses, and generalizations harvest a vast multiplicity of criteria that govern our understanding and concept of love. In effect, Proust showed through his characterization, monologue and dialogue, as well as through the plot, that the range of the experience of love renders impossible any traditional essentialist definition of it. To have discovered, explored, and artistically wrought this important truth about our conceptual life and to have shown it a full generation before philosophers stated it is not the least of Proust's accomplishments in his great novel.

PROVABILITY LOGIC

Even though "provability logic" did not come into its own until the early seventies, it has its roots in two older fields: metamathematics and modal logic. In metamathematics, we study what theories can say about themselves. The first—and most outstanding—results are Kurt Gödel's two incompleteness theorems.

If we take a sufficiently strong formal theory T —say, Peano arithmetic—we can use Gödel numbering to construct in a natural way a predicate $Prov(x)$ in the language of T that expresses " x is the Gödel number of a sentence which is provable in T ." About T we already know that it satisfies *modus ponens*:

If it is provable that A implies B , then, if A is provable, B is provable as well.

Now it turns out that, using Gödel numbering and the predicate $Prov$, we can express *modus ponens* in the language of T , and show that in T we can actually prove this formalized version of *modus ponens*:

$$Prov(\ulcorner A \rightarrow B \urcorner) \rightarrow (Prov(\ulcorner A \urcorner) \rightarrow Prov(\ulcorner B \urcorner)).$$

When we rephrase both the normal and the formalized version of *modus ponens* using the modal operator \Box , reading $\Box A$ as " A is provable in T ," we get the modal rule

$$(1) \quad \frac{A \rightarrow B \quad A}{B}$$

and the modal axiom

$$(2) \quad \Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B).$$

Indeed both the rule and the axiom are well known from the basic modal logic K .

Similarly, we can show that if there is a proof of the sentence A in T , then T itself can check this proof, so T proves $Prov(\ulcorner A \urcorner)$ —we shall call this principle *Prov-completeness*. Again, though in a less straightforward way than in the case of *modus ponens*, we can formalize the principle itself and see that T actually proves:

$$Prov(\ulcorner A \urcorner) \rightarrow Prov(\ulcorner Prov(\ulcorner A \urcorner) \urcorner).$$

When we rephrase the principle of *Prov*-completeness and its formalization in modal logical terms, we get the modal rule that is usually called necessitation:

$$(3) \quad \frac{A}{\Box A},$$

and the modal axiom

$$(4) \quad \Box A \rightarrow \Box \Box A,$$

which is the transitivity axiom 4 well known from modal systems such as K4 and S4.

Finally, one might wonder whether *T* proves the intuitively valid principle that “all provable sentences are true,” that is, whether *T* proves $\text{Prov}(\ulcorner A \urcorner) \rightarrow A$. Unexpectedly, this turns out not to be the case at all. Löb proved in 1953, using Gödel’s technique of diagonalization, that *T* proves $\text{Prov}(\ulcorner A \urcorner) \rightarrow A$ only in the trivial case that *T* already proves *A* itself!

Löb’s theorem has a formalization that can also be proved in *T*. Writing both the theorem and its formalization in modal terms, we get the modal rule

$$(5) \quad \frac{\Box A \rightarrow A}{A},$$

and the modal axiom

$$(6) \quad \Box(\Box A \rightarrow A) \rightarrow \Box A,$$

usually called *W* (for well-founded) by modal logicians.

Now we can define provability logic, which goes by various names in the literature—*PRL*, *GL* (for Gödel/Löb), *L* (for Löb), and, in modal logic texts, *KW4*. It is generated by all the modal formulas that have the form of a tautology of propositional logic, plus the rules (1),(3),(5) and axioms (2),(4),(6) given above. One can prove that rule (5) and axiom (4) already follow from the rest, so that *PRL* is equivalently given by the well-known system *K* plus the axiom $\Box(\Box A \rightarrow A) \rightarrow \Box A$.

The main “modal” theorem about *PRL*—but one with great arithmetical significance—is the “fixed point theorem,” which D. de Jongh and G. Sambin independently proved in 1975. The theorem says essentially that “self-reference is not really necessary.” Suppose that all occurrences of the propositional variable *p* in a given formula *A* are under the scope of \Box -es, for example, $A(p) = \neg \Box p$ or $A(p) = \Box(p \rightarrow q)$. Then there is a formula *B* in which *p* does not appear, such that all propositional variables that occur in *B* already appear in $A(p)$, and such that $PRL \vdash B \leftrightarrow A(B)$. This *B* is called a fixed point of $A(p)$.

Moreover, the fixed point is unique, or more accurately, if there is another formula *B'* such that $PRL \vdash B' \leftrightarrow A(B')$, then we must have $PRL \vdash B \leftrightarrow B'$. Most proofs of the fixed point theorem in the literature give an algorithm by which one can compute the fixed point.

For example, suppose that $A(p) = \neg \Box p$. Then the fixed point produced by the algorithm is $\neg \Box \perp$, and indeed we have $PRL \vdash \neg \Box \perp \leftrightarrow \neg \Box(\neg \Box \perp)$. If we read this arithmetically, the direction from left to right is just the formalized version of Gödel’s second incompleteness theorem. Thus, if *T* does not prove a contradiction, then it is *not* provable in *T* that *T* does not prove a contradiction.

The landmark result in provability logic is Solovay’s “arithmetical completeness theorem” of 1976. This theorem says essentially that the modal logic *PRL* captures *everything* that Peano arithmetic can say in modal terms about its own provability predicate. Before formulating Solovay’s theorem more precisely, we turn to the semantics of *PRL*.

Provability logic has a suitable Kripke semantics, just like many other modal logics. Unaware of the arithmetical relevance of *PRL*, Krister Segerberg proved in 1971 that it is sound and complete with respect to finite irreflexive transitive frames, and even with respect to finite trees. This completeness theorem immediately gives a decision procedure to decide for any modal formula *A* whether *A* follows from *PRL* or not. Looking at the procedure a bit more precisely, it can be shown that *PRL* is “very decidable”: Like the well-known modal logics *K*, *T*, and *S4*, it is decidable in PSPACE. This means that there is a Turing machine that, given a formula *A* as input, answers whether *A* follows from *PRL*; the size of the memory that the Turing machine needs for its computations is only polynomial in the length of *A*.

The modal completeness theorem was an important first step in Solovay’s proof of the arithmetical completeness of *PRL*. Suppose that *PRL* does not prove the modal formula *A*. Then there is a finite tree such that *A* is false at the root of that tree. Now Solovay devised an ingenious way to describe the tree in the language of Peano arithmetic. Thus he found a translation *f* from modal formulas to sentences of arithmetic, such that Peano arithmetic does not prove $f(A)$. Such a *translation f* respects the logical connectives (so, e.g., $f(B \wedge C) = f(B) \wedge f(C)$), and \Box is translated as *Prov* (so $f(\Box B) = \text{Prov}(\ulcorner f(B) \urcorner)$). Thus Solovay’s arithmetical completeness theorem gives an alternative way to construct many nonprovable sentences. For example, we know that *PRL* does not prove $\Box p \vee \Box \neg p$, so by the theorem, there is an arithmetical sentence $f(p)$ such that Peano arithmetic does not prove $\text{Prov}(\ulcorner f(p) \urcorner) \vee$

$Prov(\neg f(p))$). In particular, if we suppose that Peano arithmetic does not prove any false sentences, this implies that neither $f(p)$ nor $\neg f(p)$ is provable in Peano arithmetic.

In recent years, logicians have investigated many other systems of arithmetic that are weaker than Peano arithmetic. They have given a partial answer to the question: “For which theories of arithmetic does Solovay’s arithmetical completeness theorem still hold?” It certainly holds for theories T that satisfy the following two conditions:

1. T proves induction for formulas in which all quantifiers are bounded (like the quantifier $\forall x \leq y + z$) and T proves that for all x , its power 2^x exists. In more technical terms: T extends $\Delta_0 + EXP$.
2. T does not prove any false Σ_1 sentences.

For such theories, it is also clear that PRL is sound if we read \Box as $Prov_T$ (where $Prov_T$ is a natural provability predicate with respect to a sufficiently simple axiomatization of T). To sum up, we have the following theorem: If T satisfies 1 and 2, and A is a modal sentence, then

$$PRL \vdash A \Leftrightarrow \text{for all translations } f, T \vdash f(A).$$

This result shows a strength of provability logic: For many different theories, PRL captures exactly what those theories say about their own provability predicates. At the same time this is of course a weakness: For example, provability logic does not point to any differences between those theories that are finitely axiomatizable and those that are not.

In order to be able to speak in a modal language about such distinctions between theories, researchers have extended provability logic in many different ways, only a few of which are mentioned here. One way is to add a binary modality, \triangleright , where for a given theory T , the modal sentence $A \triangleright B$ stands for “ $T + B$ is interpretable in $T + A$.” It appears that the interpretability logic of $\Delta_0 + superexp$ is different from the interpretability logic of Peano arithmetic.

Another way to extend the framework of PRL is to add propositional quantifiers, so that one can express principles like Goldfarb’s:

$$\forall p \forall q \exists r \Box((\Box p \vee \Box q) \leftrightarrow \Box r).$$

Finally, one can of course study predicate provability logic. V. A. Vardanyan proved that the set of always provable sentences of predicate provability logic is not even

recursively enumerable, so it has no reasonable axiomatization.

Rineke Verbrugge (1996)

PROVIDENCE

The idea of “providence” has three components—fore-sight, direction, and care. It is normally found in a theistic context. In its fullest sense it means that God foresees and governs (in a word, “provides for”) the world that is the object of his care (or love). Divine providence was affirmed by Plato in his *Laws* (887–888), where he condemns the view, later held by the Epicureans, that the gods take no interest in human affairs. The most important later thought upon the subject arose in Stoicism and Christianity.

STOICS

The Stoics held a firm belief in the providence (*pronoia*) of God (or the gods). Thus, Epictetus uses an elementary form of the teleological argument to prove God’s supervision of the universe (*Discourse* 1.16). But two factors prevented the Stoics from taking a fully personal view of providence. First, they often conceived God abstractly (as a cosmic logos) and even physically (when they identified him with nature’s basic elements, air and fire). Second, and correlatively, they did not stress God’s care for persons individually, nor, as a consequence, did they allow that God accomplishes his purpose in and through the free response of human wills to his initiative. On the contrary, they equated providence with destiny or fate

(*heimarmene*). In the words of Cleanthes's Hymn to Zeus, translated by Seneca, *Ducunt volentem fata, nolentem trahunt* ("Fate leads the willing, drags the unwilling on," Epistles 107:11).

CHRISTIANITY

Our primary evidence for Christianity is the teaching of Christ himself. Christ taught that God is a Father who cares for all his children individually. Therefore, they must not be anxious or distressed; rather, they must trust God absolutely (Matthew 6:25–33, 10:29–31). Furthermore, they must approach God freely in prayer in the confidence that he will answer their requests (Matthew 7:7–11). St. Paul made two basic assertions: first, that we know through Christ that God's sovereignty is one of love through which we are "more than conquerors" (Romans 8:35–39) and second, that God accomplishes his purpose by cooperating with our wills, not by demanding our submission to a *fait accompli* (Romans 8:14–16, Philippians 2:12–13). Hence, St. Paul, like Jesus, affirms the reality of, and the necessity for, petitionary prayer.

Attempts have been made to see providence in nature, history, and individual lives.

NATURE

The theist maintains that God acts in nature both ordinarily, through those laws which science formulates, and extraordinarily, through miracles. Both modes of God's activity signify his wisdom and love to the believing mind. Furthermore, many theists, following Thomas Aquinas in his Fifth Way, believe that it is possible to base an argument for God's existence on the apparent traces of design in nature, but it must be admitted that the fact of evil constitutes *prima-facie* evidence against the existence of a Designer who is both omnipotent and good.

HISTORY

To what extent can we interpret God's purpose in terms of a "pattern," or "patterns," discernible in historical events? Here one can only summarize a general tendency among modern theologians. Most of them would say that our ability to perceive a pattern or plan is restricted to the main events of the Bible as interpreted by the prophetic and apostolic writers. Perhaps we also have a right to see a *preparatio evangelica* in the achievements of Greece and Rome, but we cannot perceive an analogous plan in either the secular or ecclesiastical history of the postbiblical era. Thus, Josef Pieper writes, "Not that he who philosophizes could reach the point of being able to identify *in concreto*

the character of an event in terms of salvation and disaster. We are moving here within the realm of the *mysterious*—in the strictest sense. And even for the believer, the history of salvation 'within' history is not to be apprehended concretely" (*The End of Time*, London, 1954, p. 23).

INDIVIDUAL LIVES

In regard to individual lives we must also distinguish between a general belief in providence and a detailed knowledge of its workings. St. Paul affirmed as a matter of faith that "we know that in everything God works for good with those who love him, who are called according to his purpose" (Romans 8:28). But in 1 Corinthians 13:12 he admits that all our knowledge of God is indirect, partial, and confused. Hence, any claim to see God's purpose in particular events is bound to be provisional and incomplete.

PSEUDO-DIONYSIUS

The writings of Pseudo-Dionysius, first cited at the beginning of the sixth century, have attracted interest partly because the writer has been wrongly identified with Dionysius the Areopagite, who was converted by St. Paul at Athens, and also with St. Denis, the patron saint of

France. Neither of these identifications, however, is possible.

While the thought of Pseudo-Dionysius was a continuation of the Christian Platonism of the early Church Fathers, it is directly influenced by the latest forms of Neoplatonism, as found in Proclus. No other early Christian writer was so clearly influenced by a particular philosopher. The influence of Pseudo-Dionysius on later theologians, philosophers, mystics, and poets was immense. John of Damascus and Thomas Aquinas were both strongly influenced by him. Peter Lombard, Robert Grosseteste, and Albert the Great also acknowledged their debt to him. The poetry of Dante Alighieri and John Milton reflects his heavenly hierarchy.

Four of his treatises—"The Celestial Hierarchy," "The Ecclesiastical Hierarchy," "The Divine Names," and "The Mystical Theology"—and ten of his letters are extant. The problem of the one and the many in the treatises is the problem of the relation of God to the universe, both visible and invisible. The basic propositions of Proclus were that every plurality participates in unity, is both one and not one, and is other than the one itself. The order of the universe is an order that depends on the ultimate unity. It is arranged in different orders of being that descend from and ascend to the first principle. This hierarchical view of the universe goes back to Plato and Aristotle and is found in Philo and the Gnostics, as well as in later Platonism. Proclus and Pseudo-Dionysius represent the final stage of the idea in the ancient world, and Pseudo-Dionysius is the chief transmitter of the idea to later times.

The four treatises exhibit the sequence of Dionysius's thought. Those on hierarchies show the descent and return of the divine goodness, "The Divine Names" shows the nature of God, and "The Mystical Theology" shows the way by which the knowledge of God may be found.

THE HIERARCHIES

"The hierarchy is a holy order, a knowledge and an activity which assimilates to the divine nature as far as possible and which through the light granted from God is raised in due proportion to the imitation of God" ("The Celestial Hierarchy" III, 1). The celestial hierarchy contemplates the divine perfection and shares in it, reflecting its light down through its several ranks: Seraphim, Cherubim, Thrones, Dominions, Powers, Authorities, Principalities, Archangels, and Angels. The members of the highest hierarchy are nearest to God and share most fully his vision and his likeness. The other members of the hierarchy become more symbolic and corporeal as they

descend. Each member of the hierarchy comes directly from God, in contrast with the emanations of Proclus, which produce one another. The Christian doctrine of creation makes the unity of the hierarchy that of spiritual communion rather than that of progressive generation. On Earth the ecclesiastical hierarchy continues the celestial hierarchy in visible form, with Jesus at the top of this hierarchy as God is at the summit of the celestial hierarchy. The members of the hierarchy in descending triads are chrism, communion, and baptism; bishops, priests, and deacons; monks, laity, and catechumens.

"THE DIVINE NAMES"

The third treatise discusses the names given to God. These names cannot describe God but must be understood in a special sense, since God is above all reason, speech, being, and name. He is above being yet the cause of being, and may be said to be only in a higher sense. His names are not derived from himself but from the manifestation of his providence. He is both nameless and many-named. He is in the world, around the world, above the world, and above the heavens. He is sun, star, fire, water, wind, dew, cloud, stone, and rock—and none of them. Knowledge of God comes through prayer, which draws men to him so that they may know his goodness. How can such a God be the sovereign creator of a world in which evil exists? Only because evil is not real but simply the absence of good. "Evil is then a deprivation, defect, weakness, disproportion, error, and the absence of purpose, beauty, life, understanding, reason and perfection." When night falls, there is nothing positive in its darkness but simply the absence of light. Evil is simply the absence of goodness.

"THE MYSTICAL THEOLOGY"

"The Mystical Theology" describes the way to the knowledge of God by the Neoplatonic method of abstracting visible and invisible qualities until one comes to the knowledge of God by negation or removal. This knowledge of God is mystical and ineffable rather than philosophical and theological, and it involves complete cessation of thought and speech. One penetrates the darkness that is above intelligible things, and in absolute silence one is united to the ineffable. God is absolutely unknowable, and the ecstasy that unites with him is both total ignorance and a knowledge beyond reason.

The distinctive quality of Pseudo-Dionysius is found in the extreme statement of two things—the unity of the world and the unity of God. The unity and order that the divine goodness imposes on the universe is described

most concretely and explicitly. The unity of God is described in negative terms that isolate it completely from all else. The extreme statement of these two opposite things enabled Pseudo-Dionysius to influence succeeding thinkers in their account of an ordered world and of a transcendent God. The opposition is inherent in all Platonism if not in all philosophy. Its explicit exposition is therefore of value.

PSEUDO-GROSSETESTE

Pseudo-Grosseteste was the anonymous author of a *Summa Philosophiae*, written between 1265 and 1275. Because of the reference in the *Summa* to Simon de Montfort's death (1265), it could not have been written by Robert Grosseteste, who died in 1253. Bartholomew of Bologna, Robert Kilwardby, and a disciple of Roger Bacon have all been suggested as the author, but there is no consensus. It does seem probable, however, that he was English and was either a Franciscan or a secular.

The *Summa*, which begins with a history of philosophy similar to that found in Bacon's *Opus Maius*, is a work of considerable subtlety and sophistication, an advanced product of the so-called Augustinian school. It holds that there is a universal wisdom in which both ancients and moderns share, perfected however by Christian revelation. Those concerned with wisdom are theosophists, to whom truth is directly revealed; theologians, who systematize and make more clear what has been revealed to the theosophists; and philosophers. The first two groups are concerned with the infallibly true, and their proper study is of matters relevant to human salvation. Philosophy, on the other hand, while it may often be in error, is completely unrestricted in its scope and may undertake to explain the natures and causes of all things whatsoever.

The *Summa* then treats the whole range of metaphysical questions in separate treatises, beginning with truth and the necessary existence of an uncreated being and ending with psychology, light, the four elements, meteors, and minerals. Its characteristic metaphysical positions are derived largely from the author's explicit hylomorphism. Every created thing is composed of matter and form. Prime matter, the mark of contingency, is not corporeal but is unextended and has three inseparable properties: It is in potency to every form; it has a desire for form; and it is privation of form. Insofar as it is privation of form it is the cause of instability; but its desire for form is a tendency toward stability. It first receives universal form, that is, substance. Substance, or substantial form, is either corporeal or incorporeal and individuates matter. It receives further perfections from other forms, so that there is a plurality of forms in any given body. This leads the author to reject the distinction (except as one of reason) between essence and existence. It also leads him to insist that the Intelligences are compounded of matter and form and differ both according to species and individuality. The human soul, like the Intelligences, is an incorporeal intelligent substance, but unlike them is capable of being joined to a body as well as of existing separately; it too is composed of matter and form. In these points, as in many others throughout the *Summa*, the author seems to be correcting what he considers the errors of Thomas Aquinas.

Bibliography

The text of the *Summa* is printed in L. Baur, *Die philosophischen Werke des Robert Grosseteste, Bischofs von Lincoln* (Münster in Westfalen: Aschendorff, 1912), pp. 275–643. Parts are translated in R. McKeon, *Selections from Medieval Philosophers* (New York: Scribners, 1929), Vol. I, pp. 290–314. An excellent analysis appears in C. K. McKeon, *The Summa Philosophiae of the Pseudo-Grosseteste* (New York, 1948). A good summary is in E. Gilson, *History of Christian Philosophy in the Middle Ages* (New York: Random House, 1955), pp. 265–274.

Richard C. Dales (1967)

PSYCHĒ

“Psychē” in Homer first means life and later means a departed life or ghost. The first identification with soul in the sense of the conscious self is found perhaps in Ionia, and the earliest full identification with the rational as well as with the emotional side of personality has been attributed to Socrates. In all this there was no opposition between soul and body. The doctrine that the soul is a prisoner in the body that Plato took from Orphic doctrine had reached Greece, perhaps from Scythia, before the time of Pythagoras, probably in association with a doctrine of transmigration. Plato, in the *Phaedo*, while recognizing that most people do not believe in survival after death (80D), propounded a view that combines the Socratic and Orphic attitudes. In the tripartite soul of the *Republic*, however, it is the rational part alone that is immortal; this was also Aristotle’s view.

The majority of the pre-Socratics regarded the universe as a quasi-living organism, and this view also found expression in Plato’s doctrine in the *Timaeus* of a world soul as a source of orderly motion in the universe. Aristotle presented a developed human and animal psychology in his analysis of the soul in the *De Anima* and elsewhere. Whereas Plato regarded the soul as a substance separate from the body, Aristotle’s final view treated it as the form of a living body. For the Stoics the soul is an aspect of the all-pervading cosmic logos, while for the Epicureans it is a combination of especially smooth atoms. Within Christian theology Augustinians follow an essentially Platonist view, while Thomists prefer Aristotle’s approach.

PSYCHOANALYSIS

The term *psychoanalysis* pertains to the theory, therapy, and method of inquiry created by Sigmund Freud (1856–1939). The origin of psychoanalysis is often traced to Freud’s *Interpretation of Dreams* (1900), but some of its key elements can be found in his earlier writings, especially his *Studies on Hysteria* (1895), cowritten with Josef Breuer.

FREUDIAN THEORY

“Freudian theory” is not a single theory but a set of smaller ones, at least some of which are familiar to most philosophers and educated people. One of the most significant and best known of these is Freud’s theory of dreams.

Freud theorized that all dreams are fulfillments of repressed infantile wishes. During sleep, these repressed wishes can enter into the dreamer’s consciousness, but only in a disguised form, after the dream censor has altered their appearance. Freud calls what survives the dream censorship the “manifest content”; what exists prior to the censorship is the dream’s “latent content.” By having a patient free associate to a dream’s manifest content, Freud hoped to determine the dream’s latent content and ultimately to glean information about a patient’s unconscious conflicts.

In *The Interpretation of Dreams*, Freud distinguishes three areas of the human mind: consciousness, the pre-conscious, and the unconscious. Consciousness contains all that we are immediately aware of; the pre-conscious contains mental contents that we can easily become aware of; and the unconscious contains mental contents that cannot be brought to consciousness except through the use of psychoanalytic therapy.

The reason that unconscious ideas cannot readily be brought to consciousness, according to Freud, is that they are repressed. Repression and the unconscious are closely linked in his early writings: “Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us” (Freud 1923, p. 15). On his early theory of the dynamic

unconscious, what is repressed is unconscious and what is unconscious is repressed.

On September 26, 1922, however, Freud read a short paper at the Seventh International Psycho-Analytical Congress, “Some Remarks on the Unconscious,” in which he indicated dissatisfaction with his theory. In an abstract of the paper (the abstract may have been written by Freud himself), it is noted that the speaker (i.e., Freud) had retold the history of the development of the theory of the unconscious and had pointed out that it had been deemed necessary to equate the dynamic unconscious with the repressed. “It has turned out, however, that it is not practicable to regard the repressed as coinciding with the unconscious and the ego with the preconscious and conscious. The speaker discussed the two facts which show that in the ego too there is an unconscious, which behaves dynamically like the repressed unconscious...” (author unknown, 1923, p. 367). The two facts are resistance proceeding from the ego during analysis and an unconscious sense of guilt.

This short paper and its abstract anticipated the publication of his *The Ego and the Id* (1923), in which Freud makes another important modification of his earlier views. Here he introduces the expression “*das Es*” (“the it”), which he explicitly borrows from Georg Groddeck; it has been translated by Freud’s English translators as “the id.” On his new theory, the structural theory, the unconscious is not equated with the repressed. All that is repressed is unconscious, but some of what is unconscious is not repressed. Some of what is in the id is repressed, but some of it is not. In addition, Freud now divides the mind into the id, ego, and superego.

The ego is held to be partly conscious and partly unconscious. It negotiates the demands of the outside world and those of the id and the superego. The id is largely unknowable, according to Freud, but we can know that it exists and know some of its properties. The id is entirely unconscious; it seeks satisfaction only of its instinctual needs, and it is the source of much psychic conflict. The superego develops out of the ego and maintains a system of ideals, values, and prohibitions.

At first, Freud tended to equate repression and defense, but in later works he classifies repression as but one type of defense. Other defense mechanisms include projection, reaction formation, sublimation, isolation, and regression. Despite his work on these other types of defenses, Freud still held that repression was the most important type of defense. In fact, he saw repression as the “cornerstone” of the whole structure of psychoanalysis.

Freud appealed to repression as the important causal determinant of parapraxes, which include memory mistakes, slips of the tongue, and neuroses, although not all neuroses. What Freud called “actual neuroses,” including anxiety neuroses and neurasthenia, are caused by events in later life and are not explainable by Freudian theory. What Freudian theory does purport to explain are the “psychoneuroses,” such as obsessional neurosis, hysteria, and depression. The psychoneuroses are said to arise from the repression of erotic wishes; their symptoms are “compromise formations”—they represent a solution to unconscious conflicts among the id, ego, and superego.

Another significant Freudian theory concerns sexual stages of development. Each of us, it is theorized, goes through four such stages. In the first year, the infant passes through the oral stage, during which its mouth is its primary source of pleasure. The focus then changes in the anal stage, where, during the next three years or so, the infant’s interest shifts to its anus. From three to five years, the child passes through the phallic period, and its genitals are of major interest. There is then a latency period lasting until puberty, when an interest in sex reemerges.

How a child reacts to events during the various stages of sexual development can help determine its adult personality. Both Freud and his followers theorized that certain personality clusters, such as obstinacy, parsimony, and orderliness, were causally linked to specific events in one or other of the infantile stages of development.

In addition to the four stages of sexual development, Freud postulated another stage, the oedipal phase, lasting roughly from age three to five years. During this period, the male child unconsciously desires to possess his mother sexually, but because of perceived threats from his father, the child develops what Freud terms the “oedipal complex.” The boy begins to fear that his father will cut off his penis and develops castration anxiety. Freud’s first published discussion of castration anxiety occurs in his discussion of the case of Little Hans (1909), whose mother told him that if he continued to touch his penis, she would ask the doctor to cut it off.

Some Freudians postulate in little girls a complex analogous to the oedipal complex, the “electra complex.” It was Carl Jung, however, not Freud, who introduced this concept. Freud himself doubted that the concept was useful and even that the phenomenon occurred (Freud 1931, p. 229).

PSYCHOANALYTIC THERAPY AND METHOD OF INQUIRY

Standard psychoanalysis, or “analysis,” has certain features that distinguish it from other types of psychotherapy. The analysand, the patient, reclines on a couch, while the analyst remains out of sight. The therapy is scheduled for four or five times per week, and, in contrast to short-term psychoanalytically oriented psychotherapy, it typically lasts three years or more.

Some analysts distinguish three phases of an analysis: the beginning, middle, and end. In the beginning phase, the analyst has a preliminary consultation with the patient, sets the fee schedule, determines (in consultation with the patient) the days and hours of analysis, and decides whether the patient is a suitable candidate for analysis. The initial phase of the analysis can last from a week or two to several months.

In the middle phase, which can last years, the heart of the analysis takes place. The patient is instructed to report childhood memories and dreams and to free-associate about their contents, saying whatever comes to mind without pause or hesitation. The main methods of inquiry used by the analyst are free association and interpretation. The analyst uses the observed data from the patient’s free associations in conjunction with other observations from the therapy sessions to form preliminary interpretations, or hypotheses, about the cause of the patient’s problems. These hypotheses are modified as the analysis progresses, with the analyst taking into account some very important factors that tend to emerge later in the analysis.

One of these factors is resistance. Freud explained the resistance that eventually emerges as the attempt to defend against remembering what has been repressed. Resistance can take different forms, including certain verbalizations, expressions of recalcitrant attitudes, and the unwillingness to free-associate. In his *Inhibitions, Symptoms, and Anxieties* (1926 [1925], p. 159), Freud refers to the patient’s resistance as “the resistance of the unconscious.”

The solution to the resistance problem is to let the patient “work through” the resistances:

One must allow the patient time to become more conversant with this resistance with which he has now become acquainted, to *work through* it, to overcome it, by continuing, in defiance of it, the analytic work according to the fundamental rule of analysis. Only when the resistance is at its height can the analyst, working in common

with his patient, discover the repressed instinctual impulses which are feeding the resistance; and it is this kind of experience which convinces the patient of the existence and power of such impulses. The doctor has nothing else to do than to wait and let things take their course, a course which cannot be avoided nor always hastened” (1914, p.155).

Another significant factor, one of “undreamt-of importance” (Freud 1940, p. 174), is transference. In the course of the analysis, the patient comes to see the analyst as the reincarnation of some important figure in his or her past and “transfers” to the analyst the negative or positive feelings formerly directed to the figure from the past. An important part of the analysis consists of the analyst’s attempt to analyze the overt manifestations of the patient’s transference in order to reach a final interpretation of the patient’s problems.

In the third and last phase of the analysis, the final interpretation is revealed to the patient: The repressed is made conscious. Yet no mere telling of the interpretation is likely to have any lasting therapeutic effect unless the ego has been strengthened enough to enable the patient’s acceptance of the interpretation.

In *Analysis Terminable and Interminable* (1937), Freud gives two criteria for terminating the analysis: first, symptom relief, with the patient overcoming his anxieties and inhibitions; and, second, the analyst’s judging that so much material has been made conscious and so much resistance conquered that there is no need to fear a repetition of the pathological processes that caused the patient’s problems. These criteria are relevant to deciding in *one sense*, Freud says, if there is to be “the end of an analysis,” but in another sense, more is required. In asking whether the analysis is at an end in this second sense, we are asking whether the analyst has had such a far-reaching influence on the patient that no further change could be expected to take place in him if his analysis were to continue. “It is as though,” Freud writes, “it were possible by means of analysis to attain to a level of absolute psychical normality,” as though the analyst had succeeded in resolving every one of the patient’s repressions (1937, pp. 219–220).

The above material contains the main outlines of Freud’s most important theories, his method of inquiry, and his therapy, but not all of his theories are covered, and important details are necessarily omitted. For brief discussions of additional psychoanalytic concepts, see B. Moore and B. Fine (1990); for more detailed discussions

of nearly all of Freud's theories, the history of the psychoanalytic movement and its development in countries around the world, and the contributions of other major figures to the development of psychoanalysis, see E. Erwin (2002).

FISSURES IN THE MOVEMENT

In the early years of the psychoanalytic movement, two serious schisms occurred: Alfred Adler (1870–1937) broke with Freud in 1911 and, at approximately the same time, Carl Jung (1875–1961) began fighting with Freud and in 1914 resigned from the International Psychoanalytical Association. These figures disagreed with Freud about several matters, but especially about the theoretical importance placed by Freud on infantile sexuality.

After breaking with Freud, Adler went on to develop his own general psychology. One of his key ideas is that the psychologically disturbed individual suffers from extreme feelings of inferiority. One of the main goals of Adlerian therapy is to eliminate this feeling of inferiority and to put in its place a feeling of community and connectedness with others. Carl Jung also developed his own type of psychotherapy and along with it a rich and complex theoretical framework that included the postulation of the collective unconscious, his theory of archetypes, and his distinction between “extroverts” and “introverts.”

One could view the theorizing of Adler and Jung as taking psychoanalysis in new directions, but their theories are so radically different from Freud's that it is doubtful that either's theory or therapy is a form of psychoanalysis at all. When Adler left—or rather was pushed out of—the Vienna Psycho-Analytical Society, he started his own group, “The Society for Free Psycho-Analysis,” but he quickly changed the name of his theory to “Individual Psychology,” a step for which, Freud said, “we are all thankful.” (“There is room enough on God's earth, and anyone who can has a perfect right to potter about on it without being prevented; but it is not a desirable thing for people who have ceased to understand one another and have grown incompatible with one another to remain under the same roof.” [Freud 1914, p. 52]). Jung, like Adler, also did not characterize his theory or therapy as a form of psychoanalysis; he preferred the name “analytical psychology.”

Long after the departure of Adler and Jung, other cracks developed in the psychoanalytic movement, but these were much smaller. One of the first of these resulted from the work of Melanie Klein, a Budapest psychoanalyst who in 1926 moved to London, where she continued her work analyzing children. Klein saw herself as contin-

uing Freud's work, although she did depart from his theories in certain respects, such as postulating the occurrence of oedipal conflicts in little girls and at an earlier time than specified by Freud's theory. Klein claimed to have made a series of important discoveries about infants, including their having a terrifying mental life, populated by beasts and monsters, and having cannibalistic urges causally linked to earlier contact with the mother's breast. Anna Freud, also working in London at the same time, strongly disagreed with some of Klein's theorizing and managed to win the support of the Vienna Psycho-Analytical Society in condemning Klein's views. The result was a bitter dispute between the “Kleinians” and London psychoanalysts who sided with Anna Freud.

A second division occurred because of the development of ego psychology, the groundwork for which was laid first by Freud's *The Ego and the Id* (1923) and developed further by Anna Freud in her work *The Ego and the Mechanisms of Defense* (1946 [1936]). Ego psychology began to flourish within the psychoanalytic tradition with the publication of Heinz Hartmann's *Ego Psychology and the Problem of Adaptation* (1958 [1939]). Hartmann and his colleagues did not see themselves as breaking with the Freudian tradition in any serious way, but they placed far more emphasis than did Freud on the role of the ego, while greatly reducing the theoretical significance of the id and superego.

Two further theoretical sharp turns occurred in the second half of the twentieth century with the development of object-relations theory and self psychology, now two of the most dominant forms of psychoanalysis.

Object-relations theory developed out of the work of British psychoanalysts, among them Melanie Klein, W. D. Fairbairn, and D. W. Winnicott. This theory is also associated with the work of psychoanalysts living in the United States, such as Otto Kernberg. According to traditional Freudian theory, there exists in each individual biological, instinctual urges, the mental representation of which are referred to as “drives.” There are two sorts of drives: the sexual drive and the drive for self-preservation. Object-relations theorists reject Freud's biologically oriented drive theory and argue that the infant is motivated not by instinctual urges but by the need to relate to another person, such as the mother. Freud, like the object-relations theorists, also used the term *object* in his discussion of infants, but he was referring not to people or things external to the infant but to the child's mental representation of them.

In contrast, object-relations theorists tend to refer to things or persons in close proximity to the infant as

“objects,” but, somewhat confusingly, the theory also talks of “internalized objects,” which clearly are not objects in the external world. One leading theorist, W. D. Fairbairn, in his *Psychoanalytic Studies of the Personality* (1952, p. 137) distinguishes between “objects” and “internalized objects” in terms of a contrast between normal and pathological psychology. In the object-relations theory, psychology becomes “the study of the relationships of the individual to his objects, whilst, in similar terms, psychopathology may be said to resolve more specifically into a study of the relationships of the ego to its internalized objects” (Fairbairn, 1952, p. 137).

In self psychology, the key theoretical concept, that of a “self object,” also has a double use; it is sometimes applied to persons and at other times to their mental representations. Self psychology was developed by Heinz Kohut and his colleagues. Kohut became known for his theory of the narcissistic personality disorder, said to have a different etiology from the “transference neuroses” talked about by Freudian theory. This disorder, Kohut claimed, can be recognized partly by observing its distinct symptoms and partly by analyzing the different types of transference that develop in the course of the analysis: a mirroring, idealizing, and twinship transference. Each of these transferences reflects the failure of a parent to respond adequately to a different type of need of the infant, such as the child’s need to confirm its own sense of greatness (the need for a “mirroring” response) or the need to experience others who resemble it (the need for a “twin” response). The result of these failures to respond is the narcissistic pathology, the subsequent failure of the narcissistic person to develop an intact self.

THE CURRENT STATUS OF PSYCHOANALYSIS

Freud’s theorizing has had an enormous influence on psychiatry, clinical psychology, art, cinema, literature, religion, anthropology, history, biography, sociology, and philosophy. The remnants of his theorizing survives through the work of individual psychoanalysts and the work of the psychoanalytic institutes and associations that exist in the United States, Great Britain, Brazil, Sweden, Finland, Mexico, South Africa, France, Austria, and in many other countries.

The work of the breakaway theorists, Alfred Adler and Carl Jung, has been considerably less popular than Freudian theory, but their theories have nonetheless been influential and are still accepted by many. Many Adlerians belong either to the International Association for Individual Psychology or to the North American Society of

Adlerian Psychology. There are also Alfred Adler institutes and schools in Chicago, San Francisco, Washington, New York, and other cities.

Many adherents of the theories of Jung belong to the International Association for Analytical Psychology. C. G. Jung institutes and societies are located in this country in New York, Seattle, Portland, Boston, Los Angeles, and other large cities, and in Canada, Australia, Great Britain, and other countries.

The continued influence of various psychoanalytic theories is important, but there is also the question of truth: How much of psychoanalytic theorizing is at least approximately true? Some of the things that Adler and Jung said were rather commonsensical and not controversial or original. If we subtract these propositions, how many of their distinctive and original claims have been shown to be true? Not very many. There are few, if any, formal empirical studies of their theories. The verdict must be that their theories remain little more than interesting but unproven conjectures.

The work of the ego psychologists, the object-relations theorists, and the self psychologists has been the subject of more empirical inquiry, but there is nothing that can be said to constitute a firm body of supporting evidence for any one of these modifications of Freudian theory. This fact has led one prominent psychoanalyst to point out that the developments in ego psychology were not prompted by new data in the psychoanalytic situation but by the recognition of obvious deficiencies in Freudian theory, and that none of these three theories has remedied the epistemological and methodological difficulties associated with Freudian theory (Eagle 1993).

The sheer quantity of the empirical evidence for Freudian theory and therapy is far greater than that of its newer psychoanalytic rivals. It includes not only Freud’s case studies but also the published case studies of many of his followers, data from anthropology and the “psychopathology of every day life,” and more than 1,500 experimental studies. There are also Freud’s arguments to consider: They are designed to show that even without the benefit of controlled studies, his theories receive powerful support from the data obtained from psychoanalytic case studies.

In evaluating the Freudian evidence, one issue concerns its subject. There is a watered-down, commonsensical version of Freud’s theories and there are the original, distinctively Freudian versions articulated and modified over the years principally by Freud himself. On the watered-down version, the unconscious exists if a person

has mental states that exist below the threshold of consciousness, whether or not these states can be brought to consciousness without the aid of psychoanalysis. Repression is said to occur whenever one tries to keep something painful out of consciousness, which obviously happens when one tries to forget a sad love affair or a hurtful insult. There are “Freudian slips,” it is said, if people make linguistic mistakes with sexual innuendoes, regardless of what causes the errors. Defense mechanisms such as “projection,” “reaction formation,” and “displacement” are said to be operative so long as certain types of defensive behavior are displayed, such as attributing to others one’s own faults or doing just the opposite of what one would like to do, no matter what causal mechanism explains the behaviors.

The evidence for some of the best-known hypotheses of the popularized, watered-down version of Freudian theory is quite strong but not new: the evidence for some sort of unconscious mind, intentional forgetting, slips of the tongue, and defensive behaviors was known to psychologists and philosophers of the nineteenth century, before Freud invented psychoanalysis. Recent historical research has shown that even many of Freud’s seemingly distinctive ideas were anticipated, not merely in some vague way but in detail, by the philosophers Arthur Schopenhauer (1788–1860), Friedrich Nietzsche (1844–1900), Eduard von Hartmann (1842–1906), and J. F. Herbart (1776–1844) (Zentner 2002).

If we limit the discussion to what is distinctively Freudian, scholars still disagree about what the evidence shows. Some still claim that the evidence gleaned from clinical case studies strongly supports some parts of Freudian theory, although that view is losing adherents even among Freudians, partly or largely due to the trenchant and systematic criticisms of the Freudian clinical evidence by the philosopher Adolf Grünbaum (2002). If, as Grünbaum argues, the clinical evidence has little probative value with respect to Freudian theory, that leaves mainly the Freudian experimental evidence, said by some to firmly support some central parts of the Freudian corpus (Kline 1981, Fisher and Greenberg 2002). Another review of the very same experimental evidence concludes that it provides almost no support for any distinctively Freudian hypothesis (Erwin 1996).

As regards Freud’s therapeutic claims, there are uncontrolled case studies and correlational studies of long term orthodox psychoanalytic therapy, but there has never been a randomized clinical trial studying its effects. Two retrospective studies of long-term psychoanalysis have been published in recent years; some analysts argue

that despite their lack of controls, they provide support for the effectiveness of psychoanalysis because of the employment of novel statistical techniques or the presence of other features that obviate the need for experimental controls. These studies and the claims on their behalf are criticized in Erwin (2002).

PSYCHOANALYTIC THEORIES, LOGICAL STATUS OF

Since psychoanalysis fails to conform to currently accepted methodological models, its prominence on the contemporary scene constitutes a challenge to the methodologist. He must either revise his canons or show the psychoanalyst the error of his ways. Both tacks have been tried, but thus far the second has predominated. This entry will be confined to methodological problems raised by psychoanalytic theory, though as we shall see, such problems cannot be pursued very far without running into questions concerning the clinical interpretation of particular cases.

CONTENT OF PSYCHOANALYTIC THEORY

Within psychoanalytic theory there are diverse strands, and the relations between them are by no means obvious. For one thing, there are theoretical ideas at different levels. Fairly close to actual clinical practice are found the concepts of repression, regression, projection, reaction formation, and transference. At a higher level there is a theoretical model of the mind in terms of psychic energy, which gets attached to various ideals, the transformations of which are governed by quasi-mechanical principles. This is, in fact, designed to be a perfectly general model of the mind, in terms of which, in the last analysis, all psychological processes and states may be conceived. At this level we have also the division of the psyche into the three systems—id, ego, and superego—together with an account of their properties and interrelations.

In addition to the distinction between levels, we have the distinction between developmental and dynamic theories. In the first group is the theory of psychosexual

stages—oral, anal, genital—according to which there is a biologically determined order, beginning from infancy, in which first one, then another, area of the body is maximally sensitive to pleasurable stimulation and according to which certain personality traits predominate as one or another stage is prolonged or transcended only with difficulty. For example, passivity and lack of initiative are associated with the oral stage, during which sensuous pleasure comes mostly from taking things into the mouth.

By contrast, the dynamic theories have to do with processes that take place, or can take place, over a short span of time or at least within the same stage of a person's life. Under this heading we have, for example, the theory of defense mechanisms, according to which the person will defend himself against dangerous impulses by various devices—going to the other extreme (reaction formation), attributing the impulses to someone else (projection), and so on. One of the reasons that the distinction between developmental and dynamic theories is important is that many of the philosophical difficulties raised about psychoanalytic theory center on the notion of unconscious psychic processes, and such processes are more central in dynamic than in developmental theories.

In order to have something fairly definite to work with, let us take the following to be an oversimplified formulation of the psychoanalytic theory of psychic conflict, which is basic to all the dynamic theories.

(1) When it is very painful for a person to be aware of the fact that he has a certain desire, he represses it (prevents it from becoming conscious). The pain may stem from a severe conflict between the desire and the person's standards for himself, from fear of the consequences of attempts to satisfy the desire, or from both.

(2) Repressed psychic material exhibits primitive, infantile features. These include the lack of sharp distinctions, which is in turn conducive to the formation of strong associations between a certain desire and many other, often irrelevant, things and a tolerance for lack of realism and for incompatibility of one's desires and thoughts.

(3) A repressed desire (which continues to exist as a desire) can be partially satisfied by happenings, in actual occurrence or in fantasy, which are associated with the object of the desire.

(4) When the substitute satisfactions themselves arouse too much anxiety, the person seeks to ward them off, often in equally derivative ways.

This basic theory is then applied to the explanation of dreams, slips of the tongue, and neurotic symptoms by studying the ways in which such phenomena constitute substitute satisfactions of repressed desires and/or defenses against such satisfactions.

An illustration of these ideas is presented by Sigmund Freud in Lecture 17 of his *General Introduction to Psychoanalysis*. A girl has, for obvious reasons, repressed a strong desire for sexual intercourse with her father. In the unconscious, various things happen to this desire and the ideas involved in it. The dread of carrying out the act generalizes to a dread of sexual activity of any sort. An association is formed between sexual intercourse and breaking a vase. The bolster at the back of the bed is pictured as the girl's father and the back of the bed as her mother. The pressure of this repressed material becomes so great that the girl develops a compulsion to go through an elaborate ritual before going to sleep at night. She arranges the vases in her room so that breakage is impossible, thus symbolically guarding against sexual intercourse, and she takes care lest the bolster touch the back of her bed, thus achieving a substitute satisfaction for her desire to keep her father and mother apart.

METHODOLOGICAL PROBLEMS

Some of the philosophical objections to psychoanalytic theory can easily be shown to have little or no force. For instance, some philosophers object that the theory postulates unobservable entities; others believe that it is self-contradictory to speak of unconscious mental processes, for what is mental is, by definition, conscious.

In answer to the first objection, it can be pointed out that this practice is common in the most respectable parts of science. Electromagnetic fields and energy quanta are as unobservable as unconscious fantasy. They are, nonetheless, scientifically legitimate because of the functions performed by the theories embodying them, a point to which we shall return. In answer to the second objection, it may be admitted that psychoanalytic theory involves some stretching of such terms as "desire" and "thought" (as in the unconscious thoughts believed to underlie the conscious content of a dream). But, again, this is standard practice in scientific theorizing. The sub-microscopic particles postulated in the kinetic theory of gases are modeled on familiar physical objects, like baseballs, except that they lack some of the properties of baseballs, like color and texture, and they possess perfect elasticity. One may as well say that it is a contradiction to speak of physical particles that have no color. Difference from familiar concepts is not in itself fatal. Again, the cru-

cial question is what can be done with the concepts thus derived.

The serious difficulties emerge when we try to determine whether psychoanalytic concepts have the kind of status that is required for scientific validity and fruitfulness. This problem has two closely related parts. (1) Do psychoanalytic terms have any empirical significance, and if they do, how can it be exhibited? (2) How can theoretical principles couched in these terms be put to an empirical test? These questions become two sides of the same coin if we make certain assumptions that are widely shared by contemporary philosophers of science. First, a term has the kind of semantic status required for science if and only if statements in which it figures have implications for what would be experienced under certain circumstances. Second, one brings out a term's empirical or scientific significance, as contrasted with its pictorial associations, by tracing out such implications. Third, it is only if statements have such implications that they can be put to an empirical test. Given these assumptions, we can deal with the two questions simultaneously. By showing how statements involving the term *repress* give rise to implications of a sort that make an empirical test possible, we will at the same time be showing what scientific significance the term has over and above any of its pictorial associations—for example, a man firmly clamping a lid down on a pot of molten metal. With this equivalence in mind, the following discussion will be explicitly directed to the second question: How can the theoretical principles of psychoanalysis be empirically tested?

There is a commonly accepted doctrine, largely derived from a consideration of physics, according to which a theory involving unobservables gets empirical significance by virtue of the fact that it, together with subsidiary assumptions, implies various general lawlike hypotheses that can be directly tested empirically. In this way the theory can be assessed in terms of the extent to which it succeeds in explaining and unifying a variety of lower-level laws that have been empirically confirmed and, on the negative side, the extent to which it does not imply lower-level hypotheses that have been empirically disconfirmed. The Bohr theory of atomic structure, which represents an atom as a sort of miniature solar system with electrons revolving in orbits around the nucleus, cannot be tested directly, for an individual atom cannot be observed. However, from the theory we can derive a variety of testable hypotheses—for instance, those concerning the constitution of the spectrum of the light emitted from a given element.

DERIVING TREATABLE HYPOTHESES

One might well expect to have difficulty deriving testable hypotheses from psychoanalytic theory. The theory represents the postulated unconscious processes mediating between events that are accessible to either introspection or observation, just as do unobservable processes within the atom in the Bohr theory.

In a typical sequence we start with conscious Oedipal desires in a child. Tentative attempts at satisfaction of the desires are met with violent opposition, and as a result the child builds up strong fear and/or horror of the realization of the Oedipal desires. Thus far, everything is, in principle, directly accessible to one or more observers. Then, according to the theory, the complex of desires, fears, and guilt is repressed, whereupon it undergoes various transformations, the exact nature of which is influenced by things that happen to the person, these things again being directly observable. In particular, the associations formed in the unconscious are largely determined by conscious experiences of the person. Finally, the unconscious complex is manifested in various ways—dreams, memory failures, slips of the tongue, compulsions, obsessions, psychosomatic illnesses—all of which are again accessible to experience. This being the case, one would suppose that the theory would yield general hypotheses to the effect that whenever strong desires of a certain kind are met with strong internal and/or external opposition, then (perhaps with the further assumption of certain kinds of intervening experiences) abnormal symptoms of certain kinds will be forthcoming. In other words, since unconscious psychic processes are supposed to provide connecting links between observables, a theory about them should imply that certain antecedent observables would lead to certain consequent observables.

In fact, however, we find little of this. Some attempts have been made to derive hypotheses about statistical distributions from parts of the theory. For example, the theory of dreams holds that dreams partially satisfy repressed desires by representing them as satisfied. It would follow from this that if a group of people were prevented from dreaming for several nights, they would then show a higher average level of tension than a control group. This hypothesis has been tested, using eyeball movement as a criterion of the occurrence of dreams. Most efforts of this sort have stemmed from relatively peripheral components of the theory; in particular, virtually nothing has been done to derive testable hypotheses specifying sufficient conditions for the occurrence of abnormal symptoms. It is only if this were done that the theory could be used for the prediction of such phenom-

ena. Perhaps this is because of the psychoanalyst's preoccupation with the treatment of particular cases rather than with controlled testing of general hypotheses.

There are other features of the situation that also make the formulation of testable hypotheses extraordinarily difficult. Psychoanalytic theory has not been developed to the point where one can give sufficient conditions for one outcome rather than another even on the theoretical level of unconscious processes. Repression is said to occur when a desire arouses great anxiety, but just how much anxiety is required? Obviously, the amount is crucial, but the measurement problem has yet to be solved. Again, given a certain level of anxiety aroused by Oedipal desires, repression is not the only possible outcome. There might, instead, be a regression to the oral or anal phase, or the libido might be redirected into homosexual channels. There are some suggestions about what makes the difference—for example, if one never fully outgrew an earlier stage, this makes regression more likely. But at present this is all rather loose.

Moreover, once repression has occurred, the repressed material may develop in a great many different ways. The fear of sexual contact with the mother may or may not generalize, and if it does, it may generalize along various dimensions. Thus, the person may develop a dread of sexual contact with anyone or only with anyone who is like his mother in some respect. A part of the complex may come to be associated with things that have little or no intrinsic connection with it, as the girl in the example cited above formed an association between sexual intercourse and the breaking of a vase. It may well seem impossible to develop principles that would take into account all the determinants of unconscious trains of thought in a way that makes possible, in principle, the prediction of such associations. This impression is reinforced by the fact that these associations are often powerfully influenced by the person's external experiences, which could not be predicted on the basis of psychological facts about him. Thus, in the above example the girl had once broken a vase and cut her finger, which had bled profusely, an incident that then was associated in her mind with the bleeding accompanying defloration.

But even if connections were strong on the level of unconscious processes, there would still remain the job of formulating sufficient conditions for the occurrence of the ultimate facts to be explained. One and the same unconscious complex, given our present powers of discrimination, may issue in a phobia, hysterical paralysis or anesthesia, obsessive concern over bodily symptoms, or a generalized feeling of unworthiness, to mention only a

few possibilities. No doubt the choice of symptom is due to other factors, but the problem has not been investigated sufficiently to yield even promising general hypotheses.

BACKGROUND FOR CLINICAL INTERPRETATION

In view of the extreme difficulty of empirically verifying psychoanalytic theory, one might ask why it should be regarded as anything other than an imaginatively satisfying fantasy. Why does it seem to have an empirical foundation? The answer is that it has significant connections with empirical facts but not connections of the sort insisted on by philosophers of science who take their models from physical theory. Psychoanalytic theory has grown out of the clinical treatment of neurotics, and in that context it has the function of providing suggestions for the interpretation of particular cases. Thus, if we are dealing with a compulsion neurosis, the theory tells us that compulsive behavior simultaneously provides substitute satisfactions for repressed desires (through the realization of states of affairs unconsciously associated with the realization of the desires) and guards against the arousal and/or satisfaction of the desire. (See the clinical case described above.)

Furthermore, the theory tells us what kinds of desires are most often repressed—incestuous, homosexual, aggressive. Also, psychoanalytic theory is associated with certain techniques—the analysis of dreams, of free associations, and of reactions to the analyst—for ferreting out repressed material in particular cases. Thus, the theory provides leads for the analyst. Insofar as it has this function rather than that of explaining and unifying testable hypotheses about the conditions under which, in general, we will get one outcome rather than another, it is no defect that it is largely made up of rather loose statements about what can happen, given certain conditions, and what can be responsible for a given symptom. In explaining an event, *E*, that has already occurred, our needs are simpler than when we are engaged in predicting or establishing general principles. In retrospective explanation we can take advantage of our knowledge that *E* has already occurred; we are reasoning backward to its sources. Therefore, provided we have a list of possible causes and some way of telling which of these are present, we have something to go on, even if each statement of possible cause is only to the effect that *C* can result in *E*. If we were setting out to predict, however, we would need a further specification of the conditions under which *C* will in fact lead to *E*. The knowledge that an unconscious desire for

and fear of intercourse with the father, plus an association between intercourse and breaking a vase, can lead to a compulsive tendency to arrange vases so as to minimize chances of breakage is general knowledge of a sort, but not of the sort exemplified by the Newtonian theory of gravitation, in which the general principles enable one to predict one state of the system from any other state of the system.

Thus, one can say that psychoanalytic theory, given the way it has developed up to now, makes contact with empirical reality through being used as a basis for explanations of certain kinds of observable occurrences and that the theory receives empirical support to the extent that such explanations are adequate. To many methodologists this situation is profoundly unsatisfying. If a theory yields predictively confirmed hypotheses, we have a strong indication that contact with something real has been made, for by thinking in these terms, we have succeeded in anticipating the course of nature. But if the theory can provide only suggestions for retrospective explanations, it is not so clear what this shows. More specifically, many have suspected that the success of psychoanalysts in devising explanations of their patients' symptoms is more a function of the analysts' ingenuity than of the soundness of their theory. It is easy to get the impression that a plausible explanation in psychoanalytic terms could be framed for any behavior, no matter what the facts. If it is not a reaction formation from overattachment to mother, then it is a projection of a self-directed death wish, and so on.

ADEQUACY OF CLINICAL INTERPRETATIONS

Clearly, what is needed is a set of objective criteria for the adequacy of an explanation in terms of unconscious psychic factors, criteria that would permit us to assess a proposed explanation on some grounds other than the way it seems to make sense of the phenomena. If and only if such criteria can be formulated can explanations of particular cases provide any empirical basis for the theory.

Within the limits of this article, we can only touch briefly on the problems involved in formulating and defending such criteria. The problems fall into three groups.

STATUS OF THE DATA. Questions have often been raised about the status of the ultimate data to which the psychoanalyst appeals in justifying an interpretation. These consist of the behavior of the patient, verbal and

otherwise, in therapeutic sessions. Criticisms have been of three sorts.

First, the data actually presented are a small sample of all the behavior engaged in by the patient in the presence of the analyst. We are almost never given any reason for supposing that this is a representative sample, that the analyst has not, perhaps unconsciously, selected those items that best support his hypothesis.

Second, a given patient is rarely, if ever, compared with controls who do not have his difficulties. Without this we cannot show that the data cited have bearing on the abnormalities to be explained. For example, if almost anyone would get annoyed when the analyst acts bored with the session, then the fact that patient *A* does so is not likely to reveal anything that is responsible for any idiosyncrasy of his.

Third, the analyst may often be guilty of contaminating the data through, perhaps unconsciously, tipping the patient off about his interpretation, thus implicitly inviting the patient to produce associations that will support that interpretation.

These are serious problems in data collection and assessment, and they will have to be solved if psychoanalysis is to become more respectable scientifically. But since it seems in principle possible to overcome them, they are less crucial for the logical status of the theory than problems in the other groups.

UNCONSCIOUS CAUSES. An explanation of *E* in terms of *C* is not warranted unless *C* actually exists. What objective tests are there for the actual existence of the unconscious psychic factors appealed to by the analyst? Analysts regularly use a number of detection procedures.

Among the things they consider significant are the following: (1) Patterns of behavior that are as they would be if *A* had a desire of which he is not conscious. For example, a seventeen-year-old girl devotes a great deal of time and energy to the small children of a youngish widower friend of the family, though she is not aware of being in love with him. (2) Patterns of feeling that have the same status. In the same example, the girl gets very depressed when the widower does not send her a birthday present. (3) Analysis of dreams and of free associations. Such analysis proceeds in a rather devious fashion and cannot be illustrated briefly. It is based on the principle that unconscious complexes influence conscious thought and fantasy, including dreaming, by producing relatively safe conscious derivatives of these complexes. (4) Final realization by the patient, after treatment, that he had the desire in question all along.

The inferences involved in the use of these procedures are extremely complex, and it is difficult to say just how conclusively anyone has ever demonstrated the existence of certain unconscious material in a given case. It is worth noting that the use of (3) and (4), unlike (1) and (2), requires the assumption of certain parts of the theory. Thus, for example, we cannot take dreams to reveal unconscious desires in the way analysts do unless we assume that dreams are formed in the manner postulated by the theory. This means that insofar as explanations that are supported in part by dream interpretation are adduced in support of the theory, we are going round in a circle.

UNCONSCIOUS COMPLEXES AND SYMPTOMS. The most difficult problem is that of showing that a given unconscious complex is responsible for certain symptoms. Granted that the girl does have a repressed desire for and dread of sexual intercourse with her father, why should we suppose that this is what led her to develop a compulsive tendency to arrange the vases in her room in a certain way before retiring? In order to answer this question, we shall have to decide what kind of explanation this is supposed to be. Freud often gives the impression that it has the ordinary pattern of an “in-order-to” explanation (“I went into the kitchen in order to get a bottle of beer” or “I went into the kitchen because I wanted a bottle of beer”), except that here the want is unconscious. But the ordinary “in-order-to” explanation carries the assumption that the agent believes that the action in question is, or may be, instrumental in the satisfaction of the want in question. Can we say that the girl unconsciously believed that preventing the vases from breaking would be instrumental in preventing intercourse with her father? A strange belief, but Freud did say that the unconscious is quite illogical. Or should we say, rather, that no belief is involved here but only an association between breaking a vase and intercourse? However this issue is resolved, this assimilation will not help us to justify the explanation, for the fundamental method of justifying an ordinary “in-order-to” explanation—getting a sincere report by the agent of why he did what he did—is not available here.

Freud might claim that an analogue is available—the realization by the patient, after treatment, that that was why she had to arrange the vases as she did. However, if one rests the adequacy of the explanation on the patient’s posttherapeutic insight, he leaves himself open to the charge of undue influence on the source of data. Moreover, circularity comes up again, for if the patient came to have this conviction as a result of being presented with

this explanation under hypnosis, this would not count in favor of the explanation. Only insight that comes after certain kinds of therapeutic interactions is relevant, and the claim that insight produced in that way is valid depends on the psychoanalytic theory about the effects that can be expected from psychoanalytic therapy. Thus, there are difficulties in construing the explanation on the model of "I went to the kitchen because I wanted a bottle of beer." On the other hand, if we take as our model an everyday explanation in terms of physical causation, like "The window broke because a baseball hit it," we will have to support it by reference to general principles to the effect that factors of the sort cited have results of the kind we are seeking to explain. And the absence of such tested generalizations in psychoanalysis has already been noted.

Thus, it would seem that before psychoanalytic theory can enjoy a firm empirical foundation, its practitioners must either develop explicit and workable objective criteria for the adequacy of interpretations of clinical phenomena in terms of unconscious factors, or do more to derive testable general hypotheses from the theory, or do both.

PSYCHOLOGISM

"Psychologism" is the term first used in Germany in the first half of the nineteenth century to designate the philosophical trend defended by Jakob Friedrich Fries (1773–1843) and by Friedrich Eduard Beneke (1798–1854) against the dominant Hegelianism. Fries and Beneke advocated a philosophical position based entirely on psychology. They held that the only instrument philosophical inquiry has at its disposal is self-observation (or introspection) and that there is no way to establish any truth other than by reducing it to the subjective elements of self-observation. Psychology becomes, from this point of view, the fundamental philosophical discipline. Logic, ethics, metaphysics, philosophy of law, philosophy of religion, and philosophy of education are all little more than psychology or applied psychology. Beneke wrote, "With all of the concepts of the philosophical disciplines, only what is formed in the human soul according to the laws of its development can be thought; if these laws are understood with certainty and clarity, then a certain and clear knowledge of those disciplines is

likewise achieved" (*Die Philosophie in ihrem Verhältnis zur Erfahrung*, p. xv).

Fries and Beneke, who viewed Immanuel Kant as their predecessor inasmuch as he defended the "rights" of experience, held, nevertheless, that he was mistaken in wanting to institute an inquiry independent of experience which would arrive at knowledge of the a priori forms of intuition and of the categories and in seeking the transcendental ground of truth—the objective validity of human knowledge. This inquiry, Fries claimed, is impossible. The critique of reason can only be a science of experience based on self-observation (*System der Metaphysik*, p. 110). In the same period Vincenzo Gioberti branded as psychologism all of modern philosophy from René Descartes on. He meant by psychologism the philosophical procedure that claimed to go from man (that is, from experience) to God and contrasted it with ontologism, which is the movement from God to man.

The doctrine defended by Fries and Beneke has some connection with certain aspects of English empiricism from John Locke to David Hume in that in both theories experience is not only the instrument of control and the criterion of the truth of knowledge but also the psychological origin of knowledge itself.

Fries and Beneke were correct in accusing Kant of rejecting psychologism, since he had posited the premises for a critique of any psychologism by distinguishing (in a famous passage in the *Critique of Pure Reason*) the *quaestio facti* of the "physiological derivation" of a priori concepts—that is, of their occurrence in the mind or consciousness of man—from the *quaestio juris* of their validity, which demands as a response the transcendental deduction. This distinction, on the basis of which Kant criticized Locke, who would have answered only the first question, is one of the pivotal points of the whole Kantian doctrine—namely, that the truth of empirical knowledge does not depend on the psychological mechanism but on a priori conditions independent of this mechanism; that the validity of the moral norm does not depend on desires or appetites but is a priori as well; and that the validity of aesthetic judgments is in turn based on taste, an a priori faculty.

Toward the middle of the nineteenth century, psychologism was defended in the very field in which it would seem most foreign—logic and mathematics. In John Stuart Mill's *A System of Logic* it is explicitly stated that introspection is the only basis of the axioms of mathematics and the principles of logic; in Mill's *Examination of Sir William Hamilton's Philosophy* logic is classified under psychology and distinguished from it only as the

part is distinguished from the whole or art from science. Many logicians in subsequent years accepted this point of view.

The Kantian point of view was developed systematically by Rudolf Hermann Lotze in his *Logik*. The psychological act of thinking is, according to Lotze, completely distinct from the content of thought. The psychological act exists only as a determinate temporal phenomenon, whereas the content has another mode of being—validity. A decade later Gottlob Frege defended the same point of view with regard to mathematics.

Never take a description of the origin of an idea for a definition, or an account of the mental and physical conditions through which we become conscious of a proposition for a proof of it. A proposition may be thought, and again it may be true; never confuse these two things. We must remind ourselves, it seems, that a proposition no more ceases to be true when I cease to think of it than the sun ceases to exist when I shut my eyes. (*Die Grundlagen der Arithmetik*, introduction)

In the last decades of the nineteenth century, the neo-Kantians argued against the psychologistic presentation of philosophy. The Baden school (Wilhelm Windelband, Heinrich Rickert) defended the independence of values from psychological experience, which could never establish their absoluteness and necessity, and the Marburg school (Hermann Cohen, Paul Natorp) held, similarly, that the validity of science, like that of ethics and aesthetics, does not depend on psychological conditions but on the laws proper to these sciences—that is, on the methodological rules that govern their construction. Cohen and Natorp held, moreover, that "thought" or "consciousness" does not designate a psychic reality subject to introspection but the objectively valid content of knowledge—the totality of the possible objects of knowledge itself and the method used in the development of the sciences.

The systematic critique of psychologism in the fields of logic and mathematics is an important part of Edmund Husserl's *Logische Untersuchungen*. His main objections are that if logical laws were based on psychological laws, then (1) they ought to be, like the latter, vague and approximate, whereas, at least in part, they are so exact that they cannot be guaranteed by an empirical element; (2) they ought to be based, like all empirical laws, on induction, which yields only a probable validity and not the apodictic certainty they manifest; (3) they ought to imply the existence of such psychic events as representation and judgment, whereas they do not con-

cern the reality of psychic life and of other facts (unlike the laws of nature, which are merely probable) but concern necessary relations independently of facts (*Logische Untersuchungen*, Vol. I, Secs. 21–24). Later in his career Husserl wrote, in terms very close to Frege's, "To refer to it [a number] as a mental construct is an absurdity, an offence against the perfectly clear meaning of arithmetic discourse, which can at any time be perceived as valid, and precedes all theories concerning it" (*Ideen*, Sec. 22). He warned against the tendency to "psychologize the eidetic"—that is, to identify essences, which are the authentic objects of knowledge, with the simultaneous consciousness of these essences (*ibid.*, Sec. 61).

The battle between psychologism and antipsychologism is sometimes fought among philosophers with the same point of view. Among the existentialists Martin Heidegger, who adopted as his method Husserl's phenomenology, intended existential analysis as the uncovering of human situations in their essence, not in their psychic occurrence (*Sein und Zeit*, Halle, 1927, Sec. 7), whereas Jean-Paul Sartre, speaking of existential psychoanalysis, seems inclined toward psychologism, although he tried to correct it by affirming that "consciousness is not a mode of particular knowledge but it is the dimension of transphenomenal being in the subject" (*L'être et le néant*, Paris, 1943, p. 17).

Within logical empiricism the argument against psychologism is one of the fundamental points of Rudolf Carnap's first work, *Der logische Aufbau der Welt*. The fundamental theses of *Logische Syntax der Sprache*, especially the principle of tolerance, are incompatible with psychologism, according to which, obviously, there could be only a single language—that determined by psychological laws. Carnap took the same line when he criticized Bertrand Russell's thesis that propositions are mental events in "Empiricism, Semantics, and Ontology." Arguments against psychologism occur frequently in the writings of other logical empiricists, though traces of psychologism can be found in the thesis, deriving from Russell and held by many logical empiricists, of the immediate, private, and incommunicable character of the sense data that are at the basis of empirical propositions.

PSYCHOLOGY

In the development of “psychology,” the study of the mental life and activities of animals and men, three phases can be conveniently distinguished—the presystematic, the systematic but prescientific, and the scientific. The presystematic, by far the longest of the three phases, is that in which men observed and reflected on human ways and embodied their reflections in aphorisms, anecdotes, and fables. Presystematic thinking is important since it has been passed down through the ages and is continually augmented by that amalgam of wisdom, superstition, and dogma that those who claim no professional competence like to describe as the fruits of their experience. The presystematic psychology of contemporary primitive groups has been recorded by anthropologists, but little is known of the corresponding ideas of the precursors of the systematic psychology of the European tradition. The doctrines of the pre-Socratic philosophers are transitional.

SYSTEMATIC PHILOSOPHY OF MIND

MIND, BODY, AND NATURE. Systematic psychology began with Aristotle’s *De Anima*, which was of outstanding importance at an early stage because it provided a solid, biologically based conceptual scheme. This involved, first, an elucidation of the concept of soul (*ψύχη*) and such related concepts as mind (*νοῦς*), which were regarded as the differentiating properties of the phenomena to be studied. Aristotle’s scheme laid down the lines along which the relationship between various manifestations of soul and mind were conceived until the seventeenth century.

Second, life and mind, being closely connected with the functioning of the body, must be conceived of in a way that does justice to the peculiar intimacy of this relationship. Aristotle paid close attention to this relationship.

Third, there is the problem of how the relationship between psychological phenomena and other phenomena of the natural world is to be conceived. Are psychological concepts and categories of explanation reducible to others? Aristotle, again, was particularly interested in this question because of the attempts of some of his contemporaries and predecessors to show that human behavior fell under the concept of motion, which had a wide applicability in the natural world.

In the exposition of the systematic period of psychology these problems will be employed not simply as a framework for expounding the main lines of Aristotle’s

system of psychology but also as a framework for picking out the main features of the most important theoretical systems since Aristotle laid the foundation of psychology.

PLATO AND ARISTOTLE. Aristotle (384–322 BCE) insisted on the widest possible definition of soul, thus returning to the pre-Platonic view that soul is virtually the principal of all life. The natural expression for a living thing was *ἐμψυχον σῶμα*—“body with a soul.” Aristotle started from the linguistic point that some bodies are so described whereas others are not and asked by what criterion this distinction was made. His answer was that it is life but that there are different levels of life. Intellect, sensation, nutrition, motion, are all forms of being alive. What they have in common, however, is a self-originating tendency to persist toward an end.

This marked both a return to and a great improvement on pre-Platonic views of soul. In early Greek thought soul was thought of simply as that which keeps a man alive and which leaves his body when he dies. It was connected with breathing. Spirit (*θύμος*), on the other hand, was thought of as the generator of movement; it was connected with the movement of the limbs and with emotional states. It was thought of as quite distinct both from soul and from mind, which was regarded as the source of images and ideas. The notion of the soul as a whole of which spirit and mind were attributes emerged only gradually.

Plato (427?–347) tried to combine the concept of the soul as a whole with a stress on the preeminence of mind, which he inherited from Anaxagoras. His account, therefore, of the soul as a whole was constantly confused by the special status that he accorded to mind. In the *Republic* he spoke of the soul as having three parts—reason or mind, spirit, and desire (*ἐπιθυμία*). But he also thought that reason was the defining property of an immaterial substance that survived bodily death whereas spirit and desire passed away with the body. Similarly, in the cognitive sphere he regarded sensation and imagination as inferior to reason and as intimately connected with the body. This represented a fusion of the Orphic belief in the survival of the soul with an exaltation of mathematical reasoning as the only way of obtaining certain knowledge, which Plato took from the Pythagoreans. He thought that in mathematics the soul grasps forms that are eternal and nondeceptive. As like can be known only by like, the soul, in its rational aspect, must also be eternal. Plato’s conviction was reinforced by such considerations as those that he adduced in the *Meno*, in which the grasp of mathematical truths was exhibited in an untutored slave. According to

Plato, this indicated that the slave was being made to remember what he had known previous to his embodiment. Thus, Plato's preoccupation with epistemology led him to make a sharp cleavage between the rational and irrational parts of the soul.

Aristotle approached the matter from a biological rather than an epistemological standpoint. Reason, spirit, and desire represented different levels of being alive. To be alive is to possess a self-originating tendency toward an end. This is exhibited at the lowest level in nutrition and reproduction. Thus, plants have a low-grade soul. Animals have sensation, locomotion, and desire superimposed upon nutrition and reproduction. Human beings, in addition, have reason, or mind, by means of which a rule or plan is imposed upon desire. By mind is meant self-direction in accordance with a rational formula.

Aristotle maintained that the lower level of soul is a necessary condition for the higher and that the possession of a higher type of soul also changes the way in which the lower functions. Because humans are rational, they feed, reproduce, perceive, and act in a manner that differs from that of animals.

Soul and body. Plato's view of the special status of reason was plausible at a time when almost nothing was known about the functioning of the brain and nervous system, for abstract thought seems to proceed with little dependence on bodily organs. Furthermore, the identity of a subject of experience through time does not seem to depend entirely on bodily continuity. There is thus a case for Plato's concept of the rational soul as some kind of active agency that inhabits the body for a brief period.

Plato thought that the rational soul inhabits the head because the head is round (the most perfect shape and, hence, an appropriate place for the seat of reason) and the part of the body nearest the heavens. It makes contact with the brain, which was conceived of as a kind of marrow encased in the skull. The irrational soul makes contact with the marrow of the spinal cord in its bony sheath. The better part of the irrational soul, spirit, inhabits the heart and functions in such manifestations of life as energy, courage, and ambition; the worse part, desire, functions below the diaphragm, in appetite, nutrition, and reproduction. The rational and irrational parts affect each other through the liver, which acts as a sort of mirror of thought.

In sleep the soul is shut up, and its motions subside. A few agitations remain, however, and produce dreams. Usually dreams are the expressions of desires that are suppressed—an interesting anticipation of Sigmund

Freud's theory of dreams. The good man controls his desires sensibly and so is not unduly disturbed by them in sleep. In the *Republic* Plato also suggested that in sleep the rational soul, if not troubled by irrational desires, can attain truths not otherwise revealed.

Plato thought of sensation as a transmission of motions. The human body receives an impression from without and responds with an inner motion. Some parts of the body—for instance, the hair and the nails—are subject to shock but do not respond with inner movements. Sense organs, however, are good conductors of motion. Thus, hearing, for instance, is the end product of a kind of shock. By means of air in the cavities of the body a blow is transmitted through the ears to the blood and brain and then to the soul. Knowledge does not consist just in sensation but in the activity of the soul in relation to what is thus transmitted. This transmission is complicated by the intervention of memory, imagination, feeling, and association, all of which act as intermediaries between reason and sensation.

Aristotle believed that there was a very intimate connection between soul and body that was a particular case of the more general relationship between form and matter. The soul is "the first actuality of a natural body furnished with organs." He used other examples to illustrate this relationship. If the eye were an animal, he said, eyesight would be its soul, this being the form or capacity of the eye. To speak of soul is to speak of a capacity or propensity to function in a certain way that depends on a certain bodily structure, or it is to speak of the actual exercise of such a capacity or propensity, which is the second kind of actuality. Thus, anger, for instance, can be the appetite of returning pain for pain or the boiling of the blood around the heart, depending on whether the dialectician or the physical scientist is considering it; there is always a biological and a psychological account to be given.

The soul, Aristotle argued, is the cause of the body in three ways. It is its efficient cause in that reference to some concept, such as desire, is required to explain movement. It is the formal cause in that behavior is explained as the exercise of a capacity or tendency. It is the final cause in that reference must be made to "the reason for the sake of which" movements of the body take place. If the behavior is explained by recourse to the rational soul, then plans and rules are imposed on desire. In choice, for instance, means are worked out and adapted to attain an end.

Generally speaking, Aristotle held that soul and body are a particular case of the more general correlatives,

form and matter. When he spoke of theoretical reason rather than practical reason, he suggested that the distinction between matter and form is again exemplified in that reason is both passive and active. But he hinted at another sort of doctrine when he also claimed that active reason comes from without and is divine. It is like a helmsman in a ship. This looks like a concession to the Platonic view of mind.

The details of Aristotle's physiology were carefully related to his idea of the levels of soul. The primary function of the nutritive soul is the absorption of nourishment, but its end is to generate another being like itself. The unity of the species is thus preserved though individual members perish. The stomach was thought of as an oven where animal heat cooks the food and blood in the heart. The heart is the seat of life, sensation, motion, and heat.

Sensation is a discriminative power from which the higher cognitive functions develop. There is the organ, the power to receive sensible forms, and the sense, regarded as constituted of both matter and form. In sensation the sense organ is assimilated to its object—for example, the eye becomes colored. But whereas in nutrition both matter and form of external objects are absorbed, in sensation only form without matter is taken in, like wax taking the imprint of a seal ring. Each sense is sensitive to one or more qualities ranging between extremes. Too little would not register; too much would destroy the organ. This was an application of Aristotle's doctrine of the mean that he developed in relation to moral conduct.

The particular senses are all developments of touch, depending on the intervention of a more refined medium. Taste, for instance, apprehends the savory properties of bodies through the intermediary of moisture; smell, the odorous properties conveyed through the air. In the transmission of sensations to the heart and in the vitality that flows from the heart, the "connatural spirits" play an important role. They were thought of as a kind of inner air quite distinct from the outer air that we breathe. Closely associated with the blood, they acted as a universal internal medium for the transmission of sensation. Besides the specific senses there is *sensus communis*, which is not a sixth sense but a generic power of sensation as such which provides unity for the sensitive soul in its particular manifestations. The ear does not see; however, the man who hears also sees, and some qualities are presented through more than one sense—for example, roundness by sight and touch. By *sensus communis* we also perceive the common sensibles of figure, motion,

rest, magnitude, and also what Aristotle called the accidental sensibles, which are the principles of association of ideas—similarity, contiguity, and the like. We also perceive that we perceive through *sensus communis*.

Imagination is a by-product of sensation. Forms provided by sensation are manipulated in the absence of physical objects. Memory is a combination of imagination and *sensus communis*. There is an image of something plus an awareness of its pastness. Recollection is rather different, for it involves the exciting of an image and the release of a whole chain of images joined by habit according to the principles of association. Imagination also provides a link between knowledge and action, for desire presupposes the imagination of an end to be attained. It may be deliberative, if influenced by reason, or merely sensitive. Desire is thus dependent on sensation and thought. In this way Aristotle was able to maintain his three levels of soul by making desire appear at two levels, depending on whether it is rational or irrational.

Psychological and mechanical concepts. Aristotle believed not only that there were certain very general concepts, such as form, matter, and change, which could be applied to everything; he also extended teleological categories of explanation—his ill-fated final causes—to all nature. Nature, he thought, was composed of natural kinds that could be classified by genus and differentia, which all had a natural place, and which all tended toward the realization of their essence. "Nature, like mind, always does whatever it does for the sake of something, which something is its end." Such modes of explanation proved singularly unfruitful when extended to the physical world. But because they were taken from the realm of life, where Aristotle, a marine biologist and the son of a doctor, was particularly acute, they fitted very well, in a general sort of way, that realm of phenomena in which they had their natural home. Aristotle was often accused by later mechanists of being anthropomorphic, but there is not much wrong with being anthropomorphic about men. Indeed, those who later attempted to explain human behavior in mechanical terms applicable to the physical world may well have made the obverse mistake to Aristotle's.

Aristotle himself, in criticizing the mechanists of his day, gave some very interesting arguments to show why the soul, which is the source of movement, cannot itself be moved. Plato had steadfastly claimed that the soul was the source of motion. In a famous passage in the *Phaedo* (98B–99D) he made clear his objection to extending mechanical explanations to cover human conduct. Plato admitted that some kind of physical account could be

given of the movements that led up to Socrates' sitting in his prison cell, awaiting his death. But he scorned the suggestion that this account would be a satisfactory explanation of the situation, for an explanation must include some reference to Socrates' reasons for being there. Plato did not, however, develop elaborate arguments against mechanical theories.

Aristotle, on the other hand, wrote his *De Anima* as part of his systematic attempt to classify the different sciences on the basis of the subject matter with which they were concerned. He was therefore very much concerned both with demarcating the field of application of various families of concepts and with sketching the ways in which they were related to each other. Movement (*κίνησις*) was only a particular type of change. He was most anxious to deny that it was either the only or the fundamental type.

Aristotle argued, first, that a logical mistake is made if the soul as a formal cause is thought of as moved in the physical sense. How can a capacity or tendency be conceived of as moving or being moved? Nor can the actualizations of soul in particular cases be properly conceived of as movements, for in practical thought the processes have unity because they go on for the sake of some end. Their particular type of unity cannot be assimilated to such physical unities as the parts of a spatial magnitude; it is more like the unity of a series of numbers. Reference to an end is a conceptual device for picking out how a series of movements are to be thought of as constituting one action; such an end is not itself an extra movement. In the case, too, of some processes of theoretical thought, such as inferring, "thinking has more resemblance to a coming to rest or arrest than to a movement." The end is, as it were, built into the meaning of the term. "Inferring," "concluding," and even "perceiving" are terms that intimate the attainment of ends or standards that are intrinsic to the processes themselves.

Concept of consciousness. Arguments of the Aristotelian type have been revived in recent times by such philosophers as Gilbert Ryle, who have defended a predominantly Aristotelian concept of mind in opposition to a Platonic or mechanical concept. Such a concept of mind is in keeping with the biological orientation of psychology that followed the impact of Charles Darwin. However, it sprang out of the post-Wittgenstein reaction against privacy as the hallmark of the mental, which had characterized most psychological theories since the time of René Descartes (1596–1650).

It is difficult for modern Western scholars to grasp that the Greeks really had no concept of consciousness in that they did not class together phenomena as varied as

problem solving, remembering, imagining, perceiving, feeling pain, dreaming, and acting on the grounds that all these are manifestations of being aware or being conscious. Historically, this emphasis on private experience presupposed the development of individualism as a social movement. The Greeks of the city-states lived in a public world of public feats and public concerns. Their word *ιδίωτης*, from which we derive the word *idiot*, was a term of disdain for a man who concerned himself only with private matters. Socrates, with his stress on individual self-knowledge and the care of the individual soul, was a moral innovator. With the conquests of Philip and Alexander the Great and the breakup of the small autonomous Greek states, this moral innovation became systematized in the codes of the Stoics and Epicureans. The ideal of individual self-sufficiency developed as a substitute for the much-lauded self-sufficiency of the city-states. Man, it was claimed, was a citizen of the world who should either discipline himself and purify his individual soul (Stoics) or slip through life unobtrusively by cutting down the possible sources of misery (Epicureans). This led to an increase of interest in the will and the emotions and to an emphasis on individual experience.

This turning inward was institutionalized by Christianity, with its stress on personal salvation and the purity of soul. Introspection vied with revelation as a source of knowledge. St. Augustine paved the way for Descartes's first certainty, *cogito ergo sum*. With Descartes the Platonic view of the soul and of knowledge was reinterpreted in the light of the rise of the mathematical sciences, but there was a difference—the stress on the certainty of our knowledge of our own mental states. Mind was no longer simply associated with reason; it was something to which we have private access and whose rational activity it is self-contradictory to doubt. This stress on privacy as a hallmark of the mental was a far cry from Aristotle's view of soul as characterized by a self-originating tendency to pursue an end. A brief mention, however, should be made of some of the intervening systems, though from the point of view of psychological theory, nothing of any great importance happened after the death of Aristotle in 322 BCE until the seventeenth century, when new systems were inspired by the rise of the physical sciences.

STOICS AND EPICUREANS. The Stoics and Epicureans provided an interesting contrast in respect to their views about the relation between soul and the rest of nature. Both attempted a monistic view, but whereas the Stoics reverted to Plato and tried to extend the concept of soul so that it permeated all nature, the Epicureans reverted to

Democritus and extended a mechanical atomistic account of nature to include life and mind.

Stoics. The Stoics thought of everything in the universe as being either active or passive; hence, there was no opposition between dead matter and soul. The ultimate substance is fire, which has different forms at different levels of being, ranging from cohesion at the inorganic level, through growth at the plant level, to life of a rational or irrational type at the animal and human level. Fire is thus the all-pervading principle of activity as well as the reason or regulator of change in the universe. Mental activity as found in men is a concentrated form of the universal reason, creatures being vehicles for the operation of this universal regulation. Hence the Stoic injunction to live according to nature, for in simple instinctive tendencies reason is often manifest in an incorrupted form.

The Stoics believed that the soul of man is a very subtle form of the all-pervasive fire, for the corporeal can be affected only by what is corporeal. The soul is affected by the body; therefore, the soul, too, must be corporeal. It combines heat, mobility, and a high degree of rarefaction. Indeed, it was more or less identified with the “connatural spirits” of Aristotle that course through the body closely associated with the blood, which are transmitted in generation, and which are similar in nature to the warm outer air, which is also essential to life. The breast is the seat of the soul.

Perhaps the most interesting and important contribution of the Stoics to psychology was their application of the Aristotelian categories of activity and passivity, which they thought to be the defining attributes of what is real, to the mind. Mental activity, they held, is characterized by assent (*συγκατάθεσις*), which can be exhibited in perception and memory, as well as in practical and intellectual judgment. This may be justified or erroneous, but truth is natural and error unnatural. When error of a perceptual, intellectual, or practical kind occurs, the explanation is to be sought in the theory of emotions or mental disturbances. Basic to this Stoic account was the notion of impulse, which covered both appetite and aversion and which operates obscurely at the level of sensation as well as at the rational level, when it is transformed into the adoption of ends for action. Emotions are thus unsuccessful attempts at full rational choice. The early Stoics left such failures unexplained; the later Stoics assigned the cause to circumstances and, therefore, to things that are beyond our power. From this came their characteristic emphasis on the assertion of will over adversity, of rational choice over irrational promptings.

Epicureans. The main interest of Epicurean psychology was its anticipation of mechanical theories of the seventeenth and subsequent centuries. Everything, Epicurus (341–270 BCE) believed, was constructed from atoms and, therefore, everything, including minds, could be explained in terms of the mechanical laws governing atoms. The soul differs from other atoms in that it is lighter and more mobile; heat is fundamental to its nature, but it is not identical with fire. It permeates the body like a subtle air and gives it life.

Sensations are effects produced in sense organs by effluxes from objects, differences in sensations being explained in terms of differences in external movements and in the configurations of the underlying atoms. Similarly, ideas are caused by atoms striking the subtle matter of the thinking soul. Incoming impressions set up other motions in the mind, making possible judgment, which is a motion of the mind superimposed upon an impression. Error occurs when impressions are accompanied by irrelevant motions of the mind. The motions of the mind can be linked together to form complex ideas by principles of association. Reason is simply the use of general ideas brought about by the fusion of images into composite pictures.

It is difficult to see how notions such as error and truth could be generated by such descriptions of mere movements of atoms. Indeed, Epicurus did nothing to meet Aristotle’s acute criticisms of mechanical descriptions of thought. He did something, however, to meet the charge of fatalism in his notorious doctrine of the swerve of the atom, which was a consequence of the self-motion postulated for all atoms. The power of the mind to incline this way or that constitutes its freedom. People are poised between pain, which is one sort of motion, and pleasure, which is an excessive reaction to pain. Between these two extremes there is an equilibrium, which is more permanently satisfying and which reason can guide men to attain. This he called freedom from disturbance (*ἀταράξια*), which is inseparable from the use of reason.

THEOLOGICAL PSYCHOLOGY. The psychology of the Greeks had always been, in varying degrees, subservient to epistemological and ethical concerns. The account of reason, for instance, or the role ascribed to the passions was a graphic way of presenting solutions to problems about knowledge and conduct. But there was also the Greek passion for speculation about the ultimate nature of things, about the One in the many, and about the status of mind in the universe and its relation to the body. With the coming of Christianity, which brought with it

the biblical account of the creation of the world, this radical metaphysical speculation abated, and the body was seen largely as something that had to be considered as a potent source of temptation. Psychological theory became almost entirely an offshoot of epistemology and ethics, for the supreme purpose of life for thinking men became the knowledge of God and the quest for salvation.

The religious preoccupations of such writers as Plotinus, Clement, and Augustine introduced, of course, a different emphasis into epistemology and ethics. This was manifest before the coming of Christianity in the work of Philo Judaeus (fl. 20 BCE–40 CE), who thought that real knowledge was a possession only of minds that had been so purified that they received divine illumination. Philo was the first systematic thinker to fuse the religious fervor of the Hebrew tradition with a selection from the conceptual schemes of Plato, Aristotle, and the Stoics. Knowledge of God and a divinely sanctioned code of conduct had somehow to be fitted into the speculative schemes of the Greeks. Because neither God nor his purposes are manifest to the senses, increasing importance was attached to inner experience as a way of knowing. Philo even wrote a treatise titled *On Dreams Sent from God*.

This shift of emphasis from the outer world to the inner world is clearly seen in the Neoplatonism of Plotinus (c. 204–270). Plato, like all the Greeks, was supremely interested in action, politics, and the external world. His theory of Forms was, in the main, explanatory—his version of the search of the Greek cosmologists for the One in the many. Even the supreme Form, the Form of the Good, was both the source of the intelligibility of the world and the supreme ideal of action. Plotinus, on the other hand, saw mystical contemplation and absorption in the One as an end in itself. Psychology therefore became harnessed to the exploration and mapping of inner experience. As G. S. Brett remarks in his *History of Psychology*: “In Plotinus, for the first time in its history, psychology becomes the science of the phenomena of consciousness, conceived as self-consciousness” (R. S. Peters, ed., rev. ed., p. 206).

With the adoption of Christianity as the official religion of the Roman Empire a place had to be found for revelation as well as for knowledge found in inner experience. Augustine (354–430) managed to combine these two sources of knowledge. Insofar as there was no revealed doctrine on a matter, he dealt with it within the framework of Platonism penetrated by Christian mysticism. For instance, the growing knowledge of the self and of God was fitted into a Christianized version of Plato’s

doctrine of reminiscence. Questions about the body, on the other hand, were dealt with by an appeal to the Scriptures. So, too, was the origin of the soul, for it was transmitted into the body when God breathed upon Adam. The lasting influence, however, of Augustine’s *Confessions* was the importance attached to introspection and private experience. No man can escape from his own experience; he can obtain knowledge, insofar as he does not rely on revelation, only by working backward to the presuppositions of his experience as a thinking being. In this approach to the mind Augustine anticipated Descartes.

A corrective to this extreme subjectivity was provided by the rediscovery of Aristotle and the meticulous transmission of his texts by Islamic theologians. The adaptation of Aristotle in the service of Christian theology reached its climax in the work of St. Thomas Aquinas (1224?–1274). But using Aristotle as a substructure to support Christian theology was not entirely straightforward. To start with, there was the problem about the status of reason, one of the most debated topics during the Middle Ages. Aristotle’s account of the Active Intellect suffered from notorious obscurities, and there was the worry about its relation to revelation as well. Furthermore, the Islamic school, culminating in Averroes, had tended to favor a mildly pantheistic interpretation of Aristotle’s doctrine of Active Intellect. Averroes held that the reasons of individuals are but fleeting manifestations of universal reason. Thomas rejected this interpretation, completely following his teacher Albert the Great (c. 1193/1206–1280).

Thomas defined intellect as the faculty of comprehension that each individual possesses as an intelligent being. Nevertheless, reason was still regarded, as by Plato and Aristotle, as the mark of man’s difference from animals and as, in some sense, superhuman. It is qualitatively distinct from sensation and any other processes that are intimately connected with the body.

Apart from this query about the status of reason, which was itself a legacy from Aristotle, Thomas tried to stick to the Aristotelian view of the soul as the form of the body. He deliberately rejected the more Platonic theory that a man is a soul using a body. It was not just respect for the authority of Aristotle that influenced Thomas. The fact was that Christianity was committed to the belief in the resurrection of the body. The intimacy of the connection between soul and body postulated by Aristotle was a better foundation for this doctrine than the more Platonic view occasioning that contempt for the body that culminated in the Albigensian heresy that the body had been created by the devil. Thomas followed Aristotle

closely in his account of sensation, *sensus communis*, memory, and imagination. What was lacking was Aristotle's stress on striving toward an end as the defining characteristic of soul. The intuitive certainties of self-consciousness explored by Augustine remained the foundation both of psychology and of epistemology.

Scholasticism has now become a byword for sustained attention to minor questions within a system whose foundations in revelation were not questioned. There is point in such criticisms. Nevertheless, the Schoolmen preserved and spread a tradition of disciplined discussion that is the lifeblood of science and philosophy. Furthermore, in psychology they handed down not only the general outlines of Aristotle's conceptual scheme but also the details of his psychological system.

The great natural philosophers were nurtured in this Aristotelian tradition even though they eventually overthrew it. At Padua, for instance, where Galileo Galilei was trained, there was a flourishing branch of the Averroistic type of Aristotelianism. Descartes was trained by the Schoolmen at La Flèche, and his *Passions of the Soul* bears witness to these early influences. Even Thomas Hobbes, one of the archenemies of Aristotelian essences, relied on Aristotle's *Rhetoric* for the details of his psychology. He merely poured a traditional content into a mechanical mold that he adapted from Galileo, Pierre Gassendi, and the ancient atomists. The Schoolmen provided the thinkers of the seventeenth century with something solid and disciplined to revolt against. And, as with most rebels, these thinkers were really revolting against a mass of assumptions that were deeply embedded in their own consciousness. Indeed, in a certain sense their revolt was only a return to other elements in their intellectual heritage—the precipitates left by the Pythagoreans, Plato, and the atomists.

DESCARTES. Descartes's view of the mind was a return to Plato, enriched by the introspective musings of Augustine and made more precise by developments in the natural sciences.

Nature and mind. The natural sciences had made leaps forward not because of a vast accumulation of new facts, though one of the features of the Renaissance had been man's turning his gaze out toward the natural world; it was, rather, because of the amazing success that had attended the application of geometry to the phenomena of the natural world.

The success of geometric thinking about nature tended to corroborate what Plato had said about the status of reason as contrasted with the senses; it also con-

vinced the new natural philosophers like Johannes Kepler, Galileo, and Descartes that the real qualities of the natural world were those which could be treated geometrically. Matter was homogeneous, as the atomists had said. Qualitative distinctions, which had been exalted by Aristotle into irreducible natural kinds, were appearances of the varying motions and configurations of the underlying bodies. The Aristotelian doctrine of form and matter was banished; so were the final causes that he had postulated in nature.

How, then, was mind to be conceived, once the Aristotelian doctrine of form and matter had been discredited? There were two obvious possibilities. One was to adopt Epicurus's view that soul and mind were configurations of light and mobile atoms. The other was to revert to the Platonic view that mind is an altogether different type of substance that inhabits the body. Descartes adopted the second course, partly because he shared Plato's view about the wonder of reason and its difference from sensation and bodily processes and partly, no doubt, because of his Christian convictions about God, freedom, and immortality.

Mind. Descartes's departure from Aristotle was much more radical in his account of the soul than in his account of the mind. Whereas Aristotle had described the soul, even in its most primitive manifestations, in teleological terms, Descartes attempted to describe all its lower functions, which were connected with the body, mechanically. His account of mind was not dissimilar in its main outlines from Aristotle's account of reason, which was the most Platonic part of his doctrine, for both accounts held that mind comes from without, furnishes the ultimate principles of thought, and may be considered apart from the body. Indeed, Descartes stated emphatically that the mind can think without a body.

For his account of mind Descartes looked into himself in the manner of Augustine, but he rejected that reliance on faith which was epitomized by the protestation *Credo quia absurdum* ("I believe because it is absurd"). Nothing that was not clearly and distinctly present to the mind was to be included in a judgment. Everything must be doubted—even mathematical truths—until a belief can be found that applies to what exists and that it would be self-contradictory to deny. Descartes's *cogito ergo sum*—his more precise rendering of Augustine's intuitive certainty about his existence as a thinking being—was the result.

Descartes explored the rest of what was intimated in this first certainty and tried to spin out of it all sorts of other truths—for example, the existence of God and of

an external world. The details of his attempted demonstration do not concern us here. They effectively established, in Descartes's view, the existence of thinking substances that were innately so constituted that they would come to form clear and distinct ideas of extension, figure, motion, and other simple natures. Ideas are all mental; as images they are presented through bodily processes, images being apparently corporeal.

Minds were thought to be passive in cognition. When a mind is thinking clearly and distinctly, its ideas correspond to the real qualities of objects. But minds are also active in volition. At the intellectual level their activity consists only in assent to the necessary connection between ideas, and volition is one of the most potent sources of error, for there is often assent when ideas are not clear and distinct. Volition is also the cause of action and is operative in attention, recollection, and fantasy.

Body-mind relation. Descartes's account of the body-mind relation was not dictated solely by Platonized Christian piety. It was equally the product of his knowledge of science and his convictions about scientific method. First, Descartes was convinced that the body is a machine and that animals' behavior could be explained mechanically, animals having no souls. He was acquainted with the discoveries of William Harvey that showed the circulation of the blood to be a mechanical process. Furthermore, mechanical models were a feature of the age. Decorative fountains were constructed with model men that were moved hydraulically and even uttered sounds like words. Descartes thought that the body contained tubes like water pipes along which the animal spirits (the up-to-date rendering of Aristotle's "connatural spirits") coursed. Because many movements of the body can be executed without conscious intentions, Descartes assumed that these could be explained in the same way as the movements of the hydraulic men. He has thus been credited with the discovery of reflex actions. He thought that all animal behavior could be explained in this way.

Second, Descartes believed in the principle of conservation of energy. The quantity of motion imparted to and conserved in a system being constant, there could be no extra source of energy deriving from volition. Thus, the relationship between body and mind had to be conceived in a way that was consistent with this principle.

Third, Descartes held that scientific explanation consisted of making deductions from relations grasped between clear and distinct ideas. Clear and distinct ideas were available of the simple natures of body (for example, extension, figure, motion) and of mind (thinking, will-

ing) but not of the relation between them. Descartes held fast to the obvious fact that body and mind interact (for when I will, it is my arm that moves; I feel pain when my body falls and not when a stone falls). But we have only a confused idea of this interaction. His account of the relationship between them was therefore only a likely story with which he was not really satisfied. It only narrowed down the point at which the crucial philosophical difficulties occurred.

Descartes knew that muscles operate in opposing pairs and that nerves are necessary for sensation and movement. He pictured nerves as tubes along which animal spirits flow. Changes in the motion of these animal spirits cause them to open some pores in the brain rather than others. When this happens, the spirits are deflected into muscles that move the body by being distended laterally and, thus, shortened. At the level of instinct and habit this process is purely mechanical. At the level of conscious intention, however, something more had to be postulated, the impact of mind on body at the crucial switching point of the spirits, the pineal gland.

Descartes supposed that in sensation motion was transmitted from the stimulus object through a medium to the sense organ and thence along the spirits in the nerves to the pineal gland in the center of the brain, where an impression was made like that of a seal on wax. This was a material image that stimulated the soul to produce a corresponding idea. Descartes gave a similar account of passions in the narrow sense of emotions and organically initiated disturbances, which have their source in the agitation of the spirits. By passions in a general sense, Descartes meant all things that *happen* to minds, including sensations, lower forms of memory, feelings, emotions, and other disturbances of reason. These he contrasted with the mind's activity. All such incoming stimuli generally give rise to an act of will. Willing again makes contact with the body at the pineal gland, and a chain of events is started in the body terminating with the movement of the muscles, which produces voluntary action.

The soul is like a pilot in a ship in that it can effect the direction but not the amount of bodily movement. Thus, Aristotle's image of active reason could be reconciled with the principle of the conservation of energy. Descartes's hypothesis that interaction between body and mind occurred at the pineal gland did nothing to dispel the philosophical perplexity about how this interaction could be conceived, and then the pineal gland later was shown to be nothing more than an obsolescent eye. Descartes was attached to this idea because the pineal

gland was the only part of the brain that was not duplicated in both halves of the brain. He was convinced that the soul, being unitary, could not affect the body at two points. His hypothesis enabled him to keep his mechanistic account of the body intact.

For a long time it has been fashionable to deride Descartes's rather disastrous form of dualism and even to suggest that he created the body-mind problem. This is a piece of intellectual insularity. Descartes was perhaps the first thinker to formulate the problem at all clearly. It would be possible to deny his basic assumption that body and mind are qualitatively distinct substances and still to claim that apart from this metaphysical extravagance his statement of the problem brought out at least two cardinal points that are involved in it. First, he obviously saw the logical incongruity of explaining mental processes, such as geometric reasoning and deliberating before action, in mechanical terms. There is a logical gap between the types of explanation used, as Aristotle had pointed out in his criticisms of the mechanists who held that the soul was moved. Descartes, in his account of the transactions that were alleged to take place at the pineal gland, must have thought that motion at this point is somehow identical or correlated with the mental activity involved in producing an idea or making an act of will. His hypothesis did much to draw attention to this logical disparity between the two types of description.

Second, Descartes's account did much to establish privacy, rather than Aristotle's criterion of purpose with plans and rules superimposed at the level of the rational soul, as the main hallmark of the mental. As has been indicated, Descartes's theory in this respect marked the culmination of a trend that can be traced back through Augustine and Plotinus to Philo. To attribute mind to something is not just to say that men act in accordance with rules and that their movements persist toward ends. It is to say that they act like this because of their knowledge of rules and because they are conscious of ends. Consciousness is crucial for picking out the obvious respect in which men differ from cunningly contrived machines. Descartes must be credited with the clearheadedness to have stood firm on this cardinal point.

SPINOZA. Benedict de Spinoza's system was a consequence of pushing Descartes's assumptions to their logical conclusions.

Nature and mind. Descartes had accepted the traditional notion of substance as that which is a cause of itself, can be conceived through itself, and needs only itself in order to exist. Spinoza (1632–1677) argued that if

this is the definition of substance and if there is such a substance, there can be only one such substance, which can be called either nature or God. Nature, so conceived, must have infinite attributes, but we know only two of them, thought and extension. God is therefore "the place of the world and the whole system of thinking." Everything is a mode or modification of God. Thus, nothing can be adequately explained unless its occurrence can be deduced from principles applying to the system as a whole.

Explanation is deductive in character and accords with mechanical principles. Unlike Descartes, Spinoza envisaged a science of psychology in which mental as well as physical phenomena could be deduced from quantitatively expressed laws. Emotions, he argued, must obey laws just as lines, planes, and bodies do. Human beings, as part of nature, must exhibit the general characteristics of all modifications of God or nature. They must be determined within a system; they must have a mental and a physical aspect; and they must exhibit *conatus*, or the striving to persist within their own being. These characteristics must now be considered in turn.

In stating that human behavior was determined within a system, Spinoza wished to oppose what he considered to be two basic illusions that human beings had with respect to themselves. The first of these was the illusion of free will. People are convinced that they have free will, he argued, because they are conscious of their actions but ignorant of their causes; thus, they conclude that they are uncaused. If stones were conscious, they, too, would believe in free will. Yet human behavior can be explained just as can the movements of stones. In both cases the explanation will consist in deducing what occurs from the laws of the system of which they both are part, ultimately the system of nature as a whole. The human body is a system of simpler elements maintained in an equilibrium, but this system is part of a broader system, not a self-contained isolable system. Adequate explanation is seeing events as part of the whole system of nature; in this system there are no final causes. Nature just is, like a vast, timeless machine.

Body and mind. How then was the body-mind relation to be conceived? Spinoza was one of the first to point to the difficulties in Descartes's pineal gland hypothesis. Spinoza's solution was to suggest that interaction does not take place for the very good reason that body and mind are correlated attributes of the same underlying substance, not distinct substances. Indeed, Spinoza says that the mind is the idea of the body. This is obvious enough at the level of immediate confused ideas that are

of bodily states. But the changes in a man's body are part of a larger system, which includes the properties of the food absorbed in nutrition. A wider knowledge of the events in a man's stomach is possible for a physiologist who can understand the laws governing them. He would see these events as part of an ever widening network of events which constitute nature. The man's feeling of stomachache, on the other hand, would be confused, fragmentary, and inadequate, an idea of an effect cut loose from its causes.

This illustrates the difference between what Spinoza called the first and second grades of knowledge. The materials of the first grade are the confused ideas of bodily states that we call feelings and sensations. These ideas are connected only by principles of association. This is the level of sense perception and imagery, of uncritical beliefs founded on animal instinct, association, and hearsay. The second grade of knowledge is rational insight. At this level rational connections are grasped as general notions develop that connect an ever widening system of events. The more abstract and general thought becomes, the nearer it approaches the thought of the Cartesian physicist and, ultimately, God's thought. There is also a third grade of knowledge, called *scientia intuitiva* by Spinoza, which is more mystical. It is a return from the abstract laws of the scientist to a grasp of the particular as illuminated by such laws. The role of the body, as that which is correlated with mind and of which mind is an idea, seemed to recede when Spinoza passed to reason, or the second grade of knowledge. Mind as the idea of the body becomes at this point almost as difficult a notion as Descartes's notion of mental activity somehow mirroring movement in the brain, for thinking is not of or about body or brain states any more than it is a form of movement which is similar to or identical with brain states.

Conative aspect of mind. Spinoza's account of mental phenomena was much less intellectualistic than that of Descartes. Indeed, in certain respects he reverted to Aristotle's emphasis on teleology and self-maintenance. Spinoza held that the most important characteristic of every modification of nature was its *conatus*, its striving to persist in its own essence. In man, as in every other natural modification, there is an inherent tendency to react to all changes in a way that maintains its characteristic unity and equilibrium. A person differs from animals in being self-conscious in this endeavor.

Spinoza employed this homeostatic postulate to rewrite Descartes's account of the passions as presented in *Les passions de l'âme*. Descartes had paid particular attention to the causal influence of animal spirits and had

left rather vague the part played by the cognitive grasp of the situation, though he generally put forward an ideomotor theory. Spinoza evinced little interest in the physiology of the matter. Instead, he developed a theory of motivation by harnessing Descartes's passions to his own homeostatic principle. He postulated that whenever a body is acted on by another body, its vitality may be increased, may be diminished, or may remain constant. The awareness of these occurrences is the mental aspect of the psychophysical states which are called emotions. There are thus three primary emotions corresponding to increase, diminution, or maintenance of bodily vitality. These are joy (*laetitia*), grief (*tristitia*), and desire (*cupiditas*). As a result of experience people tend to keep before them what will increase their vitality and remove what will decrease it. "Love" is thus defined as "joy accompanied by the idea of an external cause."

Spinoza drew a sharp distinction between the passive emotions which characterize the first grade of knowledge and the active ones which mark the second and third grades. People are passive when the cause of changes in them lies outside them. In this state of human bondage the emotions that accompany confused, fragmentary ideas are thrust on people; they tend to be sporadic, inordinate, unpredictable, and obsessive. Individuals are subject to panic, jealousy, and overmastering loves and hates. When a man passes to the second grade of knowledge, however, his vitality is increased, and there is a distinctive form of joy that goes with the use of reason. The explanation of human conduct is now to be sought within him, in his clear understanding of the world and of his relation to it. By understanding himself, including his own emotions and history, as part of the system of nature, a man can attain a kind of freedom, which depends upon his acceptance of his own nature. He is then capable of rational self-love and rational benevolence and can attain glimmerings of the greatest good which he can possess—"the knowledge of the union which the mind has with the rest of nature." The attainment of this state brings its own delight.

In making suggestions for attaining this state of blessedness, Spinoza in many respects anticipated later psychoanalytic techniques, as well as the general psychoanalytic aim of replacing subservience to irrational promptings by rational control based on self-knowledge. He thought, for instance, that many irrational reactions could be traced back to an early reaction to an object to which the present object had become associated by irrelevant similarities. Scientific understanding of this might help to dissociate the emotion from the irrelevant stimu-

lus. He was not so naive, however, as to suppose that mere intellectual understanding could free an individual from the obsessiveness of emotion. It takes an emotion to master an emotion. And Spinoza thought that seeing things “under the aspect of eternity” had a specific emotional accompaniment. Hence, the psychological shrewdness as well as the ethical profundity of his remark, “Blessedness is not the reward of right living; it is the right living itself. Nor do we delight in blessedness because we restrain our desires. On the contrary it is because we delight in it that we restrain them.”

HOBBS. Hobbes (1588–1679) already subscribed to the deductive model of geometry when he visited Galileo in 1636. He returned replete with concepts and laws that were to form the foundation of his psychology. For the idea had dawned on him, perhaps suggested by Galileo, of applying the new natural philosophy to human behavior. Of course, Epicurus had long ago sketched a mechanical theory of mind, but it was very general. Galileo had worked out the details of a new theory of motion. Could not still further consequences be deduced from the law of inertia? Harvey had deduced the theory of the circulation of the blood from mechanical postulates. Could not Hobbes apply the details of this new theory of motion to psychology and politics?

Body and mind. Hobbes did not really see any particular problem about the relationship between body and mind because for him everything was body. Even God must have a body if he exists, for “substance incorporeal” is a contradiction in terms.

Thus, “conceptions and apparitions are nothing really but motions in some internal substance of the head.” Sensation is “some internal motion in the sentient,” and pleasure is “nothing really but motion about the heart.”

In truth, Hobbes was not much worried by such philosophical niceties as whether, according to his theory, mental phenomena like thinking were being postulated as identical with or merely causally dependent on motions in the head. He was much more interested in working out a mechanical explanation of these phenomena. This is what makes his psychology of absorbing interest. It represents just about the first attempt in the history of psychology to put forward in any detail something that begins to look like a scientific theory.

Mechanical theory of mind. According to Hobbes, in sensation the sense organs were agitated by external motions without which there could be no discrimination and, hence, no sensation. The selectivity of perception

was explained by suggesting that while a sense organ retains motion from one object it cannot react to another; similarly, in attention the motion from the root of the nerves persists “contumaciously” and makes the sense organ impervious to the registering of other motions. Imagination was explained by a strict deduction from the law of inertia: “When a body is once in motion, it moveth, unless something else hinder it, eternally; ... so also it happeneth in that motion, which is made in the internal parts of man, then, when he sees, dreams, etc.... Imagination therefore is nothing but decaying sense.” This decay is not a decay in motion, which would be contrary to the law of inertia. It comes about because the sense organs are moved by other objects. This explains why dreams are so vivid, for in sleep there are no competing motions from the outside world. Thus, the longer the time that elapses after sensing an object, the weaker the imagination. Memory is imagination with a sense of pastness added to it.

This was an exciting and an ingenious theory. The difficulty about it is that the type of distinction implied in the explicanda cannot really be deduced from the mechanical postulates of the theory, for the differences between perceiving, imagining, and remembering are basically epistemological ones implying standards and criteria different from those that might be attributed to mere movements. Hobbes never faced the basic difficulties that Aristotle first formulated in his opposition to the theory that the soul was itself moved. Nevertheless, Hobbes did produce something that looked like a scientific theory. Its conceptual difficulties attend all psychological theories that attempt to translate epistemological distinctions into differences of process.

Mechanical theory of action. In the theory of action Hobbes attempted to get rid of final causes and to substitute efficient causes for them. To do this, he had to introduce the concept of endeavor, which was very different from Spinoza’s conatus. He used the term *endeavor* to designate infinitely small motions, which he postulated as occurring in the medium between the object and the sense organ, between the sense organ and the brain, and heart. His theory of motivation was that external objects transmit motions by a medium to the sense organs and from there to the brain and to the heart; this results not only in the production of images but also in some alteration or diversion of vital motions round the heart. When these incoming motions help the circulation of vital motions, it appears to us as pleasure, and the body is guided to preserve the motions by staying in the presence of the stimulating object; and conversely with pain.

Appetite and aversion are thus the first endeavors of animal motion. They are succeeded by the flow of animal spirits into some receptacle near the “original” of the nerves which brings about a swelling and relaxation of the muscles causing contraction and extension of the limbs, which is animal motion.

Hobbes thought this mechanical account of action was quite consistent with ascribing a central role to consciousness, for in Hobbes’s view all action was voluntary in the very strong sense that it is preceded by the thought of an end to be attained. He also claimed that the only way to develop a science of human nature was to look into ourselves and analyze what we find there. Hobbes found two basic motions of the mind, “the one arising from the concupiscible part, which desires to appropriate to itself the use of those things in which all others have a joint interest; the other proceeding from the rational that teaches every man to fly a contra-natural dissolution, as the greatest mischief that can arrive to nature.” Everything we do is derived from the desire for power or the fear of death. Conflict between manifestations of these basic motions of the mind leads to deliberation. In this “alternate succession of appetite and fear” the one that emerges triumphant is called “will.” “Will therefore is the last appetite in deliberation.” Free will is an illusion, for the outcome of such conflicts can be explained mechanically.

Theory of passions. On top of this mechanical ground plan Hobbes superimposed an account of the passions taken largely from Aristotle’s *Rhetoric*. They are to be distinguished by reference to the objects of appetite and aversion as well as by our opinion of attaining such objects. Ambition, for instance, is desire for office; hope is appetite with an opinion of attaining. Individual differences are due, in the main, to differences in the mobility and agility of the animal spirits. Dullness, for instance, derives from “a grossness and difficulty of the motion of the spirits about the heart.” Hobbes even had a theory of laughter, which he thought to be the expression of sudden glory caused by something new and unexpected in which we somehow discover ourselves superior to others.

Hobbes assigned a special place in his theory of the passions to curiosity, which, together with the ability to name things and hence to reason deductively, distinguishes humans from animals.

Hobbes’s account of the passions was unusual in that it was so positive. For him passions were not, as for the Stoics, imperfect reasonings; they were a particular case of motion in the natural world on which his account of human nature was erected. Nevertheless, when he dealt

with what was distinctive of man, his reason, Hobbes parted company with both naturalism and mechanical theory. The type of reason, called prudence, which enables man to satisfy his desires more efficiently, on the basis of experience, must be sharply distinguished from the reason by means of which men are able to arrive at the universal truths of geometry and philosophy.

Scope of mechanical theory. This is not the place to enter into the tortuous details of Hobbes’s nominalist theory of meaning or his conventionalist theory of truth. It is important to note, however, that in dealing with these specifically human facets of behavior, just as in his treatment of the foundations of civil society, Hobbes defended a position that stressed above all the role of artifice and convention. He even put forward a kind of contract theory of definition to parallel his social contract theory of government. These accounts were underpinned by a very crude causal theory of signs as well as by a mechanical theory of human nature. But no clear connection was ever made between the conventionalist and naturalistic elements. David Hume later tried to make such a connection by suggesting that reason was a wonderful and unintelligible instinct in human nature. Hobbes, however, more or less ignored his own mechanical theory when he dealt with geometry, law, logic, and other such artificial creations of human reason.

Thus, although Hobbes was the first thinker to develop in any detail a mechanical theory of mind, he also, more or less unwittingly, exhibited the glaring difficulties in such an undertaking. Indeed, the things in which he was most interested, apart from politics, were precisely those things which it is very difficult to accommodate within a mechanical theory.

LEIBNIZ. Gottfried Wilhelm Leibniz (1646–1716) understood much better than Hobbes the new natural philosophy; indeed, his discovery of the infinitesimal calculus contributed considerably to it. However, he resisted its mechanistic implications. Descartes had viewed nature, the animal world, and bodies as machines but had stopped short at mind; Hobbes had mechanized mind as well. Leibniz went to the other extreme and mentalized nature. In many respects he reverted to Aristotle.

Nature and mind. The *Monadology* was a brilliant synthesis of Aristotelian logic taken seriously and a variety of trends in the natural sciences. The whole Cartesian philosophy presupposed the subject-predicate view of judgment in which every proposition, when reduced to logical form, has a subject and a predicate. Moreover, the predicate was thought to be contained in the subject. The

Aristotelians thought that this common structure of language mirrored a world of substances composed of various attributes. Leibniz, like Spinoza, took the definition of substance seriously; he thought that it was the cause of itself, could be conceived by itself, and needed only itself in order to exist. But where Spinoza concluded that if this was the definition of substance, there could be only one—namely, God or nature—Leibniz concluded that the world must be composed of countless substances all exhibiting the features picked out in their definition. These monads develop according to an immanent principle that is their force or essence. Everything that will ever happen to them, their predicates, is included in their original notion. The principle of sufficient reason explains the succession of these states in time, the identity of a substance at different times being recognized by “the persistence of the same law of the series.” Now I am a substance and know by introspection that I am characterized by appetite and perception. What I know about myself must in general be a paradigm for the basic structure of all substances. But no two substances are alike. In perception they all mirror the universe from a particular point of view. There is no interaction, however. Each monad is windowless and develops because of its own immanent principle, not because of external causal influences. The monads seem to influence one another only because of the preestablished harmony of their immanent development.

This bizarre application of an ancient logical doctrine to the world accorded nicely with various new developments in the sciences. Leibniz naturally regarded it as consistent with his discovery of the infinitesimal calculus, the guiding idea of which was that a succession of states develops according to a law governing the series. The successive states of a monad flow into one another like a series of terms differing infinitesimally, their development being defined by the law of the series. This fitted well with the law of continuity, which held that *natura non facit saltus* (“nature makes no leaps”). Change is a summation of infinitesimal degrees of change. Furthermore, the recent discovery of the microscope revealed that if a piece of cheese or a seemingly empty pool is examined, each will be found to be teeming with life. Could not all nature, therefore, be alive—a vast system of monads at varying levels of development? In embryology, too, the doctrine of preformation was in vogue. The assumption that all the characteristics of an adult animal exist in embryonic form from the moment of generation supported Leibniz’s view that from the original notion of the monad all its later states and characteristics could be deduced. His conception of the essence of monads being

force or activity was connected, too, with his contribution to the dispute in dynamics about the relationship between force and mass. Leibniz held that his concept of *vis viva* or activity directed toward the future states of the monad was required by his discovery of the conservation of momentum.

The synthesis of Aristotelian logic and these trends in science made Leibniz utterly opposed to the mechanistic picture of nature and of man in which the real world was a world of bodies in motion having only primary qualities whose changes were to be explained only by reference to efficient causes. What is real, he claimed, is not what is mathematically measurable but our experience of activity and perceiving. Nature, as well as man, is characterized by appetite and perception. Final causes are reconciled with the laws of motion by the principle of sufficient reason, which governs the unfolding of the immanent nature of the monads. The difference between substances is only one of degree of clarity in perception and of self-consciousness in appetite. Bare monads have a minimum of perception and appetite. Their perception is confused, and their appetite is blind. Souls, or conscious monads, have memory, feeling, and attention. Animals, or, rather, the dominant monads of animals, are examples. Rational souls, or spirits, are self-conscious; unlike brutes, which are “empirics” and are aware only of particulars, they can reason and understand necessary truths. Extension is only an appearance, the way in which low-grade monads appear to us; the laws of motion are just appearances of the laws of appetite which depend ultimately on God’s choice of what is best. Aristotle and Galileo are reconciled, but Galileo’s and Isaac Newton’s laws are, at best, laws of appearances.

Concept of mind. Leibniz’s concept of mind or soul was articulated in what he said about perception and appetite. He regarded perception as marvelous because it cannot be conceived of as an action of the object on the percipient, for the monads are windowless. Perception is better regarded as the expression of a plurality in a unity. One thing may be said to express another when there is a constant and regular relation between what can be said about the one and about the other. It is thus that a projection in perspective expresses its original. The monads are perspectives of the universe from different points of view. Expression is thus the genus of which perception, animal feeling, and intellectual knowledge are species.

Leibniz combined this highly metaphysical account of perception with some shrewd objections to John Locke’s tabula rasa theory of the mind. He held that the senses provide us only with instances and by themselves

cannot provide the sort of universal knowledge that we have in science. The mind is active and categorizes experience by means of which it interprets the testimony of the senses. The proper analogy for the mind is not a tabula rasa but a block of veined marble. In this doctrine Leibniz harked back to Aristotle's active reason and laid the foundation for Immanuel Kant's categories. Locke, he argued, had in fact tacitly admitted this in postulating mental operations that are known by reflection.

Leibniz maintained that Locke was wrong in saying that the mind does not always think. We have an infinite number of perceptions of which we are not aware. Habituation and wandering attention, as well as the smallness of the perceptions, explain our failure to notice them. Our attention is often drawn to a sound that has just occurred and that we would not otherwise have consciously noticed, although we registered it. "These insensible perceptions are also the signs of personal identity and its constituents; the individual is characterized by traces of his previous states which these perceptions preserve by connecting them with his present state." They are also the means of recollection. They explain decisions that seem arbitrary to us, like turning to the left rather than to the right; they explain frequent feelings of uneasiness which are not intense enough to be felt as pain. These insensible perceptions, he argued, are "as much use in pneumatics as is the insensible corpuscle in physics." Both are beyond the reach of our senses, and there are as good grounds for believing in one as in the other. Since "nature makes no leaps," these insensible perceptions must accord with the law of continuity. "All this brings us to the conclusion that observable perceptions come by degrees from those which are too small to be observed."

Although Leibniz confused some rather different things in this doctrine—for example, unconscious perceptions, minute perceptions that summate like the noise of waves in the roar of the sea, and confused perceptions—he prepared the ground for the concept of unconscious mental processes which was to prove so important in nineteenth-century thought, and he anticipated later investigations of subliminal perception and "determining tendencies." This shows how a highly speculative theory can lead to the emphasis on facets of experience which may be very important but which have previously been disregarded.

Leibniz's emphasis on appetite as the other main characteristic of monads was a welcome change from the intellectualism of Descartes and Locke. However, Leibniz made no detailed empirical derivations from this notion to match the derivations made from his concept of per-

ception. It had more affinities with Spinoza's "conatus" than with Hobbes's "endeavor," although it was really the Aristotelian conception of the formal and final cause brought up to date and made compatible with dynamic theory. His concept can best be elucidated by quoting him; he calls his concept by the Aristotelian term "entelechy," which is "a power mediating between the simple faculty of acting and the definite or effected act. It contains and includes effort. It is self-determined to action, not requiring to be aided, but only requiring not to be inhibited. The illustration of a weight which stretches the cord it is attached to, or of a bent bow, may elucidate the notion."

Soul and body. Leibniz believed that every living creature is composed of a vast number of special organic structures each developing in its own characteristic way; they are all so coordinated and mutually complementary, however, that together they act as an individual. The unity is the soul or the dominant monad; the multiplicity is the body or assemblage of bare monads. The monads of the body all have their own activity, and they are represented or mirrored in the perceptions of the dominant monad or mind. The mind has no power to interfere with or penetrate the forces that it seems to direct. The activities of the monads of the body subserve the dominant activity of the mind as the players of an orchestra, each playing independent parts, subserve the performance of the symphony, and the symphony is the resultant harmony, which has been preestablished. The manifold activities of the bare monads thus combine to bring about the end of the dominant monad. The body depends on the mind in the sense that the reason of what happens in the body is to be found in the mind (compare to Aristotle's view of soul and body).

Thus, Leibniz reverted to a view of mind and nature which was basically Aristotelian, but he transformed the Aristotelian entelechy by giving it the basic hallmarks of Cartesian mind—thinking and willing as experienced from within. Furthermore, he pressed the emphasis on privacy much further than Descartes by claiming that the monads are windowless and that everything that will ever happen to them is contained in their original notion.

There was, however, another radically different concept of mind which developed out of Descartes's stress on privacy and incorrigibility as the hallmarks of mental states. This was that of British empiricism, which culminated in Hume and the associationists.

HUME. The contribution of Hume (1711–1776) to psychology was not very extensive in its details because his

theorizing about the mind, like that of George Berkeley and Locke, was mainly a way of doing epistemology. And there were special reasons, deriving from his epistemological position, for his eschewing speculation about the relationship between mind and body and the general status of mind in nature. Nevertheless, his general concept of mind was of considerable historical importance. It was the first thoroughgoing attempt to eliminate spiritual substance altogether, and it was the first theory to make reason subservient to the passions and to extol the importance of instinct and habit. It was also the first attempt to develop a Newtonian theory of mind and to erect the principles of the association of ideas into scientific postulates—an undertaking which considerably influenced David Hartley and hence the course of associationist psychology.

Hume's predecessors. John Locke (1632–1704) took from Descartes the assumption that we are confronted with our own ideas, not with things, and that some kind of certainty is both desirable and attainable. He rejected, however, Descartes's doctrine of innate ideas and adopted a Baconian version of empiricism. He postulated simple ideas of sense that made their imprint on the passive tabula rasa of the mind. Once ideas got into the mind, Locke's theory more or less followed Descartes's, for he believed that the active spiritual substance within intuitively relations between ideas, the relations which form the foundations of knowledge. Locke, however, did not stick consistently to his "way of ideas." For example, he asserted, like Descartes, that we have intuitive knowledge about our own existence as selves and "sensitive" knowledge of things existing independently of our perceptions of them. They are material substances that support "powers" to produce in us ideas of primary qualities, which are real properties of the things in question, and secondary qualities which are not real.

George Berkeley (1685–1753) stuck more consistently to the way of ideas and eliminated material substance, of which we have and could have no idea because it is a logical absurdity; the representative theory of perception; and the distinction between primary and secondary qualities. He claimed, however, that we have "notions," rather than ideas, of ourselves as active agents and of other minds, including God. We also have a notion of our own causal activity. Berkeley relied on this notion to distinguish ideas of sense from ideas of imagination, for having eliminated the concept of a thing independent of our perceptions, Berkeley had to have a criterion for distinguishing what are commonly called things from the mere coexistence of qualities; imaginary objects, for

instance, appear to us as clusters of coexisting qualities. Thus, he claimed that when we see objects, it is God talking the divine sense language and producing ideas in our minds; when we imagine objects, we are doing the producing ourselves and have a notion of our own agency in so doing. Berkeley's stress on the activity of the mind contrasted strongly with Locke's tabula rasa.

Hume simply stuck rigorously to the way of ideas and eliminated Berkeley's "notions." There was no simple idea of material substance, of ourselves and others as spiritual substances, of God, or of causal agency. All that was left, therefore, as genuine components of the mind were ideas themselves and certain links between them. Hume likened the mind to a theater "where several perceptions successively make their appearances, pass, repass, glide away," and to a political organization in which the members come and go but the principles of organization—the principles of the association of ideas—persist.

Hume's contributions. Hume was the first to attempt an explicit distinction between images, which he called impressions, and what we would now call sensations—he called them ideas. He regarded them as two sorts of perceptions. Impressions could not be distinguished from ideas in a Lockian way by their relation to an external object. For Hume, following the way of ideas, disclaimed any possibility of knowledge of a world of objects existing independently of our perceptions. And, because he ruled out notions, Berkeley's appeal to awareness of our causal agency in producing ideas of imagination was not open to him. Of course, like Berkeley, Hume agreed that what we call things exhibit a certain constancy and coherence; they resemble past clusters of qualities. We assume independent existence in order to connect past with present perceptions. But, he argued, we can no more demonstrate the existence of a world independent of us than we can demonstrate that pleasure is preferable to pain.

There are, however, subjective criteria for making the distinction between images and sensations, which is all that remains once belief in a world of independent objects has been ruled out. These are the criteria of vividness and order. Hume suggested that ideas could be picked out because they were faint copies of previous impressions. In other words, impressions are both more vivid than ideas and prior to them. But he gave counterexamples to both these criteria—those of vivid ideas in fever or madness and of forming an idea of a color that had never previously been presented as an impression. In the case of fever or madness Hume suggested that the imagination transfers the vividness of an impression to

an idea. Similarly, our belief in an external world is a work of the imagination.

Hume's recourse to the imagination was of cardinal importance in his account of the mind because it linked his theory of knowledge with his rehabilitation of feeling. It has often been remarked that one of the main features of Hume's philosophy was a reversal of the roles hitherto ascribed to reason and feeling. He brought over into epistemology his ethical theory, which he adapted from Francis Hutcheson's theory of moral sense, that moral judgments are based on feeling. "Reason is, and ought always to be, the slave of the passions." This moral sense was the product of biological properties inherent in the species; it had its counterpart in our judgments of matters of fact and existence. Reasoning is "nothing but a wonderful and unintelligible instinct in our souls." Our belief in the reality of causal connections or in the existence of an external world or that the future will resemble the past are instinctive and indemonstrable. "Nature, by an absolute and uncontrollable necessity, has determined us to judge as well as to breathe and feel." The categories used by scientists in their theories, such as continuity and causality, are largely products of the imagination.

Hume stressed facets of human nature that had been largely neglected since Aristotle. He postulated an original fabric of human nature consisting of various propensities not unlike that of later instinct theorists. He also extolled the place of habit in conduct, not simply in explaining such developed forms of behavior as obedience to government but also in explaining the origin of some indemonstrable beliefs. For instance, he held that the idea of causal connection could be analyzed into the elements of priority in time of event *A* to event *B* and constant conjunction of event *A* with event *B*, together with a conviction of the necessity that *B* must follow *A*. As there was no impression of this necessity given in experience, Hume attributed our belief in it to habit or a "determination of the mind" brought about by experience of such constant conjunction and the force of the imagination.

The passions. Appropriately enough, the details of Hume's psychology consisted mainly of an elaborate and highly complex theory of the passions, stated in Book 2 of his *Treatise of Human Nature*. One of Hume's tasks was to rehabilitate the passions, the natural feelings of decent people, from the Puritans' distrust and the rationalists' disregard. He also had to demolish sophisticated theories, deriving from Hobbes, in which all passions were regarded as forms of self-love. Whereas Bishop Butler attacked psychological hedonism in order to establish the

supremacy of conscience, Hume refuted the hypothesis of self-love in order to make way for his rival hypothesis of innate benevolence and sympathy.

He also regarded the sensations of pleasure and pain as part of the original fabric. In a passion one of these sensations is accompanied by an affection. The direct affections include desire and aversion, joy and grief, hope and fear. The difference between these depends on the character of the expectation of good or evil. Desire is for present good, joy for assured good in the future, and hope for probable though remote good in the future. Hume thought that through experience these affections, together with the sensation of pleasure or pain associated with them, can become associated with an object. This generates such indirect passions as pride and humility, when the object is ourselves, or love and hate, when the object is other people. Benevolence and malevolence, however, are not derived from love and hate. Hume classed them as direct and instinctive.

Sympathy occupied a role in Hume's theory of passions somewhat similar to imagination in his theory of belief. The idea of another person's feeling is said to be associated with the idea of oneself, and the required liveliness is thus imparted to the otherwise neutral conception of another person's joy or sorrow.

The idea of the self played an important part in Hume's intricate account of the passions. Like the idea of causality, it presented a serious problem for analysis, for we believe strongly in the reality of both of them. Yet, Hume argued, there was no simple impression of sense from which these ideas derived. Introspection revealed only "some particular perception or other, of heat or cold, light or shade, love or hatred, pain or pleasure." What we call self must therefore be "a bundle of perceptions." Like Locke, Hume then went on to compare the self to an oak, a vegetable, or any type of organism which maintains itself through change by virtue of its relations. Another apt analogy is the self-maintained unity of a political association. But Hume maintained that the unity of this bundle, which makes it a "connected heap," is associative, not real; there are no grounds for ascribing to it the simplicity and permanence which are required for real unity. Perceptions are loose, separate, perishing existences. There can be no real links between them. The problem is to explain how we come to believe that there are.

Hume made the same type of move in relation to the idea of self that he made in the case of causality. He demonstrated that if the way of ideas is followed, there is no ground in experience for believing in the reality of the self; he then embarked upon some speculative psychology

to explain how we come to have this belief. He suggested that members of the bundle are related to one another in a specific way in time, the order being preserved by memory. The members have the relations of resemblance and cause and effect between them. But cause and effect is not a real relation; thus, no real unity characterizes the self. We come to believe in it because of the “felt smoothness” with which we pass from one idea to another once the associative links have been established.

Nature and mind. Although Hume’s adherence to the way of ideas ruled out wide speculations about the place of mind in nature, there was a highly imaginative idea behind his positivistic system. Hume regarded himself as the Newton of the sciences of humankind. He made frequent references to his pursuit of the experimental method and thought his rigorous interpretation of the way of ideas to be thoroughly consistent with Newton’s methodological canons of economy and simplicity in explanation, testability of hypotheses, and refusal to postulate occult causes. Hume stressed that once we have arrived at the original fabric of human nature, it is futile to attempt to satisfy any further our intemperate desire to search for other causes.

But Hume did not emulate Newton merely in his methodology. He also regarded his concepts in the psychological sphere as parallel to Newton’s concepts in the physical. His simple impressions were the equivalent of Newtonian atoms, and his principles of association were likened to the “gentle force” of Newton’s principles of gravitational attraction. Indeed, Hume regarded imagination and, perhaps, sympathy as cohesive forces. When imagination works according to the associative principles of resemblance, contiguity, and cause and effect, the result is what Hume called the understanding. When it works capriciously, the result is fancy. Of course, the principles of association were as old as Aristotle, though Aristotle’s principles were not the same as Hume’s. Hobbes, too, had made use of them, though he believed that thought which was guided by desire or which exhibited a plan was more important. However, in Hume’s system for the first time they were looked upon as important *scientific* principles governing the working of the mind. This conception was taken up by Hartley in his theory of vibrations and developed into the associationist school of psychology.

Hume’s theory was also important in the history of psychology because it firmly established psychology as the science of the contents of consciousness. Although Descartes’s first certainty was rejected in relation to its content, what persisted was the assumption that a man

has some incorrigible sort of knowledge about his own mental states. Hume rejected Descartes’s search for simple natures, which appear to the mind as clear and distinct ideas, as the foundations of science. Instead, he postulated simple impressions of sense, perishing existences about which we can be certain provided that we make no inferences beyond them. Because Hume, like Locke, consistently confused psychology with epistemology, two parallel traditions developed from his work. On one hand, there was the search in epistemology for sense data which could provide an incorrigible basis for a system of knowledge; on the other hand, there was the development of introspective psychology whose task was envisaged as cataloguing the contents of the mind, analyzing them into simple units, and attempting generalizations about the links between these units which explained the generation of complex ideas and states.

Body and mind. Hume, understandably enough, had little to say about the relationship between mind and body. Body, according to his theory, stood for another bundle of impressions. He did not even connect the idea of self with impressions of bodily states, which might have been an obvious move if he had looked seriously for specific impressions, from which the idea of self is derived. In the Humean tradition William James, for instance, later suggested that the idea of self was intimately connected with impressions of breathing, cephalic movements, and the like. But Hume made no such suggestion. He noted the inexplicability of the fact that “the motion of our body follows upon the command of our will.” “Will,” he suggested, was another name for the strongest motive (compare to Hobbes’s account). But we simply have to accept these *de facto* connections between events. To speculate further would be to postulate occult causes and thus to sin against both Newtonian methodology and the way of ideas.

KANT. It would be very difficult to sketch the contribution of Kant (1724–1804) to psychology within the framework previously used, partly because he made very little direct and explicit contribution to psychology and partly because his Copernican revolution in philosophy involved a radical reformulation of questions asked under such a framework. Furthermore, though Kant’s concept of mind may, in fact, be extremely important insofar as it delimits the sphere of empirical psychology, those who developed empirical psychology in fact paid little heed to the implications of Kant’s position. Perhaps that was a pity, for Kant made a sustained effort to separate epistemology from empirical psychology, and until these two are clearly distinguished, there will continue to be confu-

sion in this area, as is demonstrated in the genetic psychology of Jean Piaget. Nevertheless, Kant's influence on psychology was largely negative and indirect; thus, only a short exposition will be given of those parts of his critical philosophy which seem relevant to psychology.

First and foremost, Kant rejected the notion of the empiricists that what is called mind could be explained as the product of ideas arising from experience and systematizing themselves according to laws of association. Kant maintained that the mind must be regarded as a structure regulated by principles of its own activity. These principles could not be arrived at empirically, for they were presupposed by any empirical investigation, including psychology. They could be arrived at only by critical philosophy, which asked the question "What must be presupposed for our experience to be possible?"

Kant was particularly interested in two realms of experience—Newtonian science and the autonomous morality of thinkers of the French Revolution. Kant attempted to reconcile the rationalism of Christian Wolff and Leibniz with the empiricist position of Hume by postulating an active mind whose nature was to impose a structure on experience to make it intelligible. This structure was composed of the categories used by scientists, such as substance, cause and effect, and continuity, which Hume had assigned to the imagination; Kant attributed the structure to reason, which synthesizes the data of sense. The content is provided by the senses, but the form is provided by reason. Thus, what we call nature is in part the work of mind. It is composed ultimately of things-in-themselves, whose real nature must be forever unknowable. We, too, must exist as noumenal selves, as things-in-ourselves. Of course, Hume was right in maintaining that we have no impressions of such selves. At best, we have intimations of such selves behind the appearances in our moral experience as active rational beings.

Human beings have empirical selves insofar as they have bodies and psychic functions—for example, sensation, imagery, feeling, purposes—which depend on embodiment. Such selves can be known by inner sense, and their manifestations can be investigated empirically; Kant called such a study anthropology. Kant made his mark on the history of introspective psychology by imposing on these phenomena the tripartite division—knowing, feeling, and willing—worked out in his *Critique of Judgment*. But he did not note anything particularly novel about the phenomena thus investigated, although he did declare that such investigations could never be properly scientific. He was convinced that science involved quantification and that since the phenomena

studied by anthropology could not be subsumed under mathematically expressed laws, psychology could at best be a collection of descriptive material classified under the headings that he suggested. Thus, Kant's extrapolation of Newtonian physics as the paradigm of all sciences had the negative effect of making it incumbent on those who wanted to develop psychology as a science to attempt the quantification of the phenomena to be studied. The result was Gustav Theodor Fechner's psychophysics, Johann Friedrich Herbart's attempt at mathematical laws of consciousness, and countless other premature attempts at quantification.

Another result of Kant's analysis was an increase of interest in the problems connected with the self. The controversy about the existence of a pure self and whether it was a proper object of study occupied most thinkers during the nineteenth century. Of much more importance for psychology, however, was Kant's doctrine that there can be no science of human actions, though its importance has seldom been recognized by those who are committed to empirical psychology. Human actions are the product of human reason, deliberation, and choice, and Kant held that insofar as a man's reason is involved, his behavior is not explicable in terms of the mechanical laws of nature. He acts freely and is determined only by rational laws of his own creation. This was similar to Spinoza's doctrine of freedom and activity. It raises all sorts of problems about the relationship between reason and emotion and between mind and body, problems that Kant did not seriously tackle. His concept of a rational being as a noumenon which was somehow related to a phenomenal embodied self was a metaphysical model that dramatized difficulties connected with the mechanical explanation of thought and rational action which Descartes had used a different model to depict. Kant laid more stress on the concept of will and rational action than did Descartes, but both men picked out a crucial problem for the development of psychology to which no satisfactory answer has yet been given.

TRANSITION FROM PHILOSOPHY TO SCIENCE

The history of psychology as thus far reviewed is in the main a history of the philosophy of mind, and the issues discussed have been mainly philosophical issues. The rest of the history, however, will be concerned with the slow but progressive disentanglement of psychology as an empirical science from philosophical speculation.

Although it is possible to consider Aristotle's *De Anima* as the transition from presystematic to systematic

psychology, the transition from philosophy to empirical science cannot be pinpointed so precisely. This was not so much a transition as a process of differentiation. Indeed, it began with Aristotle, but it becomes unmistakable in the psychologies of Descartes and Hobbes, both of whom were affected by the impact of Galileo's physics. Both framed hypotheses about the physical and physiological mechanisms of consciousness and behavior that were in principle testable by observation and experiment. From Descartes and Hobbes the main line of development in empirical psychology was through the British empiricists Locke, Berkeley, and Hume.

EIGHTEENTH-CENTURY BRITISH PSYCHOLOGY.

Locke's new way of ideas laid the foundations for the twin doctrines of sensationism and associationism. The theory was that the mind is composed only of sensations and mental images (mental images being faint copies of sensations), that all complex percepts or ideas are formed through association, and that all trains of thought arise through association. Locke's analysis of mind was not so simple as that. He included ideas of reflection, abstract ideas, and the self, or possessor of sensations and ideas. Berkeley contested the existence of abstract ideas and furthered the development of associationism by giving an associationist explanation of the perception of the third dimension of space—another hypothesis that was to become the subject of experimental study. Hume further refined sensationism by eliminating the self on the basis of the negative result of his attempt to observe it by introspection. The next important step was taken by Hartley, who proposed a neural basis of conscious processes. His hypotheses, too, could in principle be tested by observation and experiment. Further refinements and elaborations of associationism are to be found in the works of James Mill, J. S. Mill, Thomas Brown, and Alexander Bain. The associationist doctrines spread to the Continent and as experimental psychology later returned to England and went to the United States.

A second major influence on the advance of psychology toward the status of an empirical science was provided by the biological sciences, notably in the evolutionary doctrine of Darwin. This influence was later to prove one of the causes of the disruption of associationist psychology.

Hartley. While David Hartley (1705–1757) was practicing medicine, he made many observations of psychological interest and wrote his major opus, *Observations on Man, His Frame, His Duty, and His Expectations* (1749). It was a thoroughgoing attempt to provide a neurophysio-

logical basis for the mental processes of sensation, imagery, and association. Influenced by Newton's *Opticks*, he proposed an explanation of conscious experience and association in terms of vibrations transmitted through nerves, which were conceived of as solid fibers, thus breaking from the earlier conception of nerves as hollow tubes for the conduction of the animal spirits. For every kind of sensation there are different kinds of vibrations or vibrations differently located; corresponding to images or memories, there are vibratiuncles, miniature vibrations that can persist after the larger vibrations have subsided and which form the physical substratum of memory. The associative processes occur by virtue of the fact that if two stimuli occur simultaneously and produce two corresponding vibrations in two regions of the brain—say, vibration *A* arising from a visual stimulus and vibration *B* arising from an auditory stimulus—the repetition of only the visual stimulus producing vibration *A* will arouse vibration *B* in the absence of the original stimulus that produced *B*. This is a simple translation into neurophysiological terms of the traditional principle of association of ideas, explaining, for example, the association of thunder with lightning. Hartley further advanced associationist theory by suggesting ways in which some of the several special laws of association—contiguity in space, contiguity in time, contrast, and similarity—could be reduced to the single law of association by temporal contiguity. He also offered a more detailed account than had yet been given, in terms of association, of the formation of general ideas.

Brown. As professor of moral philosophy in Edinburgh, Thomas Brown (1778–1820) delivered a series of lectures subsequently published under the title *Lectures on the Philosophy of the Human Mind*. Though not himself an associationist, he made very important contributions to the theory of association, which he preferred to describe as suggestion. Two of his ideas were of especial importance. First, he distinguished between simple suggestion, which is association in the commonly accepted sense, and relative suggestion, which is not in any sense an associative process but is a process that was later to be described by Charles Spearman as the “education of relations.” Second, Brown formulated the secondary laws of association—the principles of recency, frequency, duration, liveliness, and so on. These were later to become the subject of innumerable experimental studies.

NINETEENTH-CENTURY BRITISH PSYCHOLOGY.

Brown's philosophy was severely criticized by Sir William Hamilton (1788–1856) in his *Discussions on Philosophy and Literature* (1852) and his *Lectures on Metaphysics and*

Logic (posthumously published in 1859–1860), but Brown was defended with no less force by J. S. Mill in *An Examination of Sir William Hamilton's Philosophy* (1865). Hamilton, who was professor of logic and metaphysics at Edinburgh from 1836 until his death, had been greatly attracted by German philosophy and contributed to the rise of the British idealistic school of philosophy later to be represented by T. H. Green and F. H. Bradley. This school, deriving its inspiration from the intellectualist and idealist thought of G. W. F. Hegel and other Continental philosophers, had no common ground with the mechanistic empiricist and physiological approach of the British psychologists, but in its criticism contributed to the refinement, as well as the demise, of associationism. It was Bradley who, in attacking the atomistic features in associationism, phrased the dictum “Association marries only Universals.” This theme was to be developed in an original way in G. F. Stout's doctrines of noetic synthesis and relative suggestion.

James Mill and John Stuart Mill. Associationism reached its zenith in the work of James Mill (1773–1836). An economist and historian rather than a philosopher or psychologist, he learned his philosophy—hedonistic utilitarianism—from Hartley. His psychology, however, was a refinement of Hartley's and his analysis of mind was much more acute. *The Analysis of the Human Mind* appeared in 1829. Mental life was reduced to sensory elements, and the development of complex ideas was explained by the principle of association. Mill gave a clearer account than had Hartley of the way in which the several laws of association could be reduced to the single law of contiguity. He refined previous accounts of emotional experience in terms of sensations. Like Hartley, he attempted to apply the principles of associationism to the explanation of the complex phenomena of conscience and religion.

John Stuart Mill (1806–1873), his son, was a more subtle and acute philosopher than his father. He was certainly more disposed to take seriously any objection to a theory he wished to defend. In his rational and reasonable way he was inclined to make concessions that resulted in his rejecting the original theory. He sacrificed simple hedonism by conceding that pleasures might differ in quality. He gave up associationism by introducing the concept of mental chemistry—the idea that mental compounds, like chemical compounds, might exhibit properties not deducible from the properties of the elements. This breach in the associationist defenses was to be widened later by doctrines of creative synthesis and Gestalt qualities and the biological concept of emergent

evolution—ideas all at variance with pure associationist doctrines. J. S. Mill was less concerned with sensationism as a psychological doctrine than with its philosophical counterpart, phenomenalism—the description of material things and the physical world in terms of sense data or “permanent possibilities of sensation.”

Bain. Though in the associationist tradition, Alexander Bain (1818–1903) was less interested in the philosophy of mind than in psychology as an empirical science. He was emphatic in his demand that psychology should be cleared of metaphysics. His *Manual of Mental and Moral Science* (1868) was virtually a textbook of empirical psychology. It was a condensation of his two major works, *The Senses and the Intellect* (1855; rev. ed., 1894) and *The Emotions and the Will* (1859). He was thoroughgoing in his insistence on the need for a physiological basis for psychology not merely in general terms but in terms of known physiological facts, about which he made it his business to be well informed. As far as this implied a philosophy of mind, it found expression in his formulation of the principle of psychophysical parallelism. Especially important were his accounts of habit formation and learning. His treatment of habit was in large measure the inspiration behind the eloquent chapter on this topic in William James's *Principles of Psychology*. E. L. Thorndike and other “learning theorists” owe to Bain the first clear formulation of the law of effect, the principle that responses are ingrained by the reward of pleasure. Even his sillier theories contributed to enlightenment. One of the silliest theories in the history of psychology—that maternal love is based on the pleasurable tactile sensations experienced from contact with a baby—foreshadows the subtler theories of Freud concerning erogenous zones in the body and, more remotely, the “releaser mechanisms” of the ethologists. Bain's associationism was not an ideology. It was merely that he had assimilated the dominant features of the current psychological climate of opinion.

Two other developments were to complete the transformation of psychology from a branch of philosophy into an empirical science: (1) the impact of the theory of evolution and (2) the establishment of laboratories for experimental psychology. The theory of evolution had its origin in England in the work of Darwin; the idea of laboratories for experimental psychology came chiefly from the Continent.

EVOLUTIONARY PSYCHOLOGY. Darwin's theory of evolution as set out in his *Origin of Species* (1859) was a very large theory, but it was a scientific, not a philosoph-

ical, theory. It was supported by an enormous body of empirical observations. Theories of evolution date back to antiquity. Charles Darwin's grandfather Erasmus Darwin had adumbrated a Lamarckian theory of evolution. Alfred Russel Wallace anticipated Darwin's theory by a few months. Herbert Spencer (1820–1903), who had propounded philosophical and psychological theories of evolution for some years before the appearance of the *Origin of Species*, was accordingly well placed to capitalize on Darwinism in the development of his own ambitious “synthetic philosophy.”

Darwin (1809–1882) himself wrote on distinctively psychological topics. His *Descent of Man* (1871) discusses the similarities between the mental processes of man and of animals. His work *Expression of Emotions in Man and Animals* gives an evolutionary interpretation of changes in features and postures and assigns biological utility to these changes. The evolutionary approach stimulated many studies by amateur and professional naturalists. G. J. Romanes (1848–1894) collected evidence for the continuity of development from the animal to the human mind, and Sir John Lubbock (1834–1913) was among the first to use laboratory techniques in the study of insects. Laboratory studies like these were to be developed later on a grand scale by such American comparative psychologists as E. L. Thorndike and R. M. Yerkes.

Galton. Sir Francis Galton (1822–1911), the versatile cousin of Charles Darwin, contributed to meteorology, anthropology, anthropometry, and psychology and to the development of statistical and other metric methods in psychology. Among his major interests was the inheritance of mental characteristics, for the study of which he devised ingenious methods. He stressed heredity as a determinant of mental life and behavior. His records of the behavior of twins are reminiscent of the Leibnizian concept of a preestablished harmony. According to his records, twins can behave exactly like two clocks each causally insulated from environmental influences and from each other, behaving similarly and thinking in unison almost entirely in consequence of the similarities of their innate constitution. His major psychological works were *Hereditary Genius* (1869) and *Inquiries into Human Faculty* (1883). He set up the first two English psychological laboratories—the first at the International Health Exhibition of 1884 and the second in the South Kensington Museum. He pioneered the application of physical and psychometric tests in schools.

Ward and Stout. Philosophical psychology was to feel the impact of the new biological approach. James Ward's revolutionary article on psychology in the ninth edition

of the *Encyclopaedia Britannica* (1886) mounted a devastating attack upon associationism, recasting psychology in terms of a “psychoplasm,” or “presentational continuum,” which, like bodily tissues, undergoes progressive differentiation and integration. Ward's distinguished pupil Stout wrote *Manual of Psychology*, a standard text for some three decades, in 1898. This was described as being written from a genetic point of view; thereafter, almost every textbook of psychology had a biological orientation.

EMPIRICISM IN EUROPE. The empiricist philosophy was introduced into France by littérateurs and essayists like Voltaire and Denis Diderot, not by philosophers or psychologists. Voltaire had lived in England from 1726 to 1729, and so was in a position to introduce British ways of thought in philosophy into the intellectual life of France. Diderot had a clearer understanding of British empirical psychology. He particularly interested himself in the mental life of persons deprived of one sense—for example, sight.

The first of the French empiricist philosophers to contribute to sensationism was Étienne Bonnot de Condillac (1715–1780). Diderot had been concerned with the mental life of persons deprived of one sense; Condillac started from the imaginary case of a person deprived of all senses except one. He took the case of a statue endowed only with the sense of smell, selecting smell because of its relative simplicity. From this he proceeded to add other senses and to explain in sensationist terms attention, memory, imagination, and reason. He attached no importance to association. He believed that the experience of one sensation after another is *ipso facto* a comparison of the two and that the occurrence of the unpleasant sensation constitutes the will to terminate the sensation. Condillac's sensationism was perhaps the simplest and most elegant form of the doctrine in the history of psychology. His views are set out in the *Traité des sensations* (1754).

Claude-Adrien Helvétius (1715–1771), author of a volume of essays titled *De l'esprit* (1758), was a minor social and political philosopher who seized upon Locke's empiricism and concept of the tabula rasa to defend an extreme doctrine concerning the equality and perfectibility of men. His basic thesis was that all differences between men are due to differences in experience and education. All error was due to passion or ignorance.

The doctrines that Helvétius derived from Locke were to return to England in the works of William Godwin, especially in his *Political Justice* (1793). Like

Helvétius, Godwin taught that all men are equal at birth and that their subsequent differences were due to experience and education. Voluntary actions originate in opinions, which can be changed by rational persuasion. Vice is error, which can be corrected. In Helvétius and in Godwin the association of empirical philosophy with an intellectualist hedonism is displayed in its most extreme form.

Through Condillac the influence of Locke spread to Italy and Switzerland. In Italy this influence is to be seen in the teachings of several all-but-forgotten writers. In Switzerland, Charles Bonnet (1720–1793) of Geneva was the outstanding figure in empirical philosophy. His chief work in psychology was the *Essai analytique sur les facultés de l'âme* (1760). Although he followed Condillac for the most part, Bonnet differed chiefly in the importance he attached to physiological explanations.

GERMAN PSYCHOLOGY AND EXPERIMENTATION. Throughout the seventeenth, eighteenth, and early nineteenth centuries German psychology was dominated by the philosophical doctrines of Leibniz, Kant, and Hegel, each of whom contributed to a rationalist idealism very unfavorable to the development of psychology as a science.

Hegel. Georg Wilhelm Friedrich Hegel (1770–1831) has received scant attention in the histories of psychology, understandably so since his form of rationalism is the most extreme antithesis to the empiricist philosophy that had favored the development of psychology as an empirical science. He is, however, not without importance in the history of psychology.

One of Hegel's theses was that it is a mistake to suppose that complex phenomena are explained only by reference to simpler phenomena, that we can, for example, understand religion in its developed form by the study of cults of primitive people or that we can understand man only through the study of lower forms of animal life. In this he challenged what had long been and still is a basic principle of comparative psychology, but Hegel's thesis survives in the view of psychologists who hold that the proper study of humankind is man and that we should begin with civilized man in advanced societies. It lives on in the contention of Freudian psychologists that the evidence for infantile sexuality can be appreciated only in the light of adult sexual behavior.

Equally important for psychology is the Hegelian dialectical progression—thesis, antithesis, synthesis. When this progression is stated as an empirical observation of movements of thought and action, not as a metaphysical principle or a principle of logic, it illuminates

many sequences in the history of politics, philosophy, and science. A dialectical progression is illustrated in the fate of Hegel's own philosophy. Its influence in Germany was short-lived. His rationalistic thesis issued in an empiricist antithesis, Wundtian experimental psychology. The dialectical progression is illustrated by the British vogue for Hegelianism among philosophers who found in it an antithesis with which to confront the prevailing empiricist philosophy and psychology. The progression is illustrated by the sequence from Hegel's idealist thesis to the antithesis of dialectical materialism that was to become a central tenet of communist philosophy. Although it provides no comprehensive philosophy of history, the concept of dialectical progression affords a rather more subtle and articulate account of historical movements than conventional, commonsense accounts in terms of "the swing of the pendulum."

Hegel's doctrines were associated with, and conferred philosophical status upon, a widespread romantic and mystical philosophy of nature according to which everything in nature had some spiritual and symbolical significance. The influence of this philosophy of nature persisted far into the nineteenth century and in the biological sciences favored vitalistic, as opposed to mechanistic, accounts of mind, body, and nature. Psychologists divided progressively into two groups. The first comprised the philosophers—that is, those who primarily taught philosophy and whose philosophy of mind contained much metaphysics. The second group consisted of natural scientists whose approach was from mathematics, physics, and the biological sciences. The distinction is not sharp, since romanticism and metaphysics were in the air that every German student, even students of the natural sciences, breathed.

The first steps in the transition from the philosophy of mind to scientific psychology were taken when Kant challenged psychologists to show that their subject could claim scientific status. This challenge was taken up by Herbart, Ernst Heinrich Weber, and Fechner. That it could be an experimental science was argued by Weber, Fechner, Johannes Müller, Hermann von Helmholtz, and others. Wundt finally established it as a science that required a distinctive kind of laboratory.

Herbart. Johann Friedrich Herbart (1776–1841) set out to establish a basis for psychology other than that of the prevailing "faculty" psychology associated with Christian Wolff (1679–1754), a disciple of Leibniz and precursor of Kant who was much less distinguished than either. Herbart tried to show that the laws describing mental process could be put into precise mathematical form.

Herbart's first achievement was the grafting of associationism onto a rationalist metaphysical root. The soul was retained, serving the traditional function of giving unity to the mind, but the data of empirical psychology were, as in associationism, sensations and ideas. In Herbart's system ideas were not just passively associated. They interacted by attractions and repulsions in accordance with which they were drawn into or forced out of consciousness. The behavior of ideas in Herbart's psychology resembles that of the "reals" in his pluralistic metaphysics. Two "reals"—for instance, *A* and *B*—differing in quality, tend to disturb each other because of their difference, but each also tends to preserve itself by resisting the disturbing effect of the other. This principle of self-preservation is reminiscent of the Spinozistic doctrine that "everything that is in itself endeavors to persist in its own being" and, when applied in Herbart's psychology, foreshadows the concept of homeostasis that was to be current in psychology a century later.

Herbart's account of the way in which ideas enter consciousness and are expelled from it represents a phase in the history of the theory of the unconscious midway between Leibniz and Freud; his concept of the apperceptive mass, a system of ideas bound together by mutual attraction, was still current when psychoanalytic writers were developing the concept of a mental complex. Herbart's metaphysics and mathematics were to be forgotten, and he did not contribute directly to the development of psychology as an experimental science. His most lasting influence was in the field of educational psychology, chiefly in the application of his theory of apperception to the process of learning.

Lotze. Rudolf Hermann Lotze (1817–1881) succeeded Herbart in the chair of philosophy at Göttingen. His most influential work was his *Medizinische Psychologie* (1852), the first systematic work on physiological psychology and one of the very few written by an author qualified in both physiology and philosophy. Against the then prevailing view he defended the thesis that every mental phenomenon has its physiological counterpart and that the laws which apply to inorganic matter also apply to organic matter. Final causes, vital and mental forces, and the soul itself can act only through mechanical causation. He insisted, however, that physiology alone cannot explain mental phenomena. Lotze is best known in psychology for his doctrine of local signs, a contribution to the theory of space perception.

Weber and Fechner. Experimentation and the use of quantitative methods in psychology were greatly advanced by Ernst Heinrich Weber (1795–1878) and

Gustav Theodor Fechner (1801–1887), who were colleagues in the University of Leipzig and who both taught Lotze.

Weber taught anatomy and physiology. His early work *De Tactu* (1834) reported studies demonstrating the difference between muscle sense and touch. These studies were extended to pain, pressure, and temperature, through which emerged the concept of thresholds and the famous law that has come to be called Weber's law. This states that the smallest increment in a stimulus required to produce a difference in the sensation experienced is not an absolute amount but is relative to the magnitude of the stimulus in question. Like most German scientists of his time, Weber was to some degree under the spell of the current metaphysics and the romantic philosophy of nature, but neither of these influenced his experimental studies. His metaphysics and his science were kept apart.

With Fechner the case was different. Fechner's intellectual life was a pilgrimage from physics and chemistry, through physiology and medicine, to metaphysics and mysticism. From an early age he had been preoccupied with the problem of the relation between matter and spirit. He was attracted to a form of panpsychism according to which not only man and the lower animals have consciousness but also the earth and the other planets—indeed, all material things. In this view all souls are parts of the soul of the universe.

Fechner concluded, on the obscurest of grounds, that the mystery of the relation between mind and body would be resolved by ascertaining the quantitative relations between stimuli and sensations. He suggested that Weber's law could be put into a quantitative form. Weber's law thus became the Weber-Fechner law, according to which the relation between stimulus and sensation is expressed in the formula $S = k \log R$ where *S* is the experienced intensity, *R* is the physical intensity, and *k* is a constant for the particular sense in question. For the verification of this law Fechner designed what are known as the psychophysical methods. These methods have been used in the most tedious of laboratory exercises to which many generations of students of experimental psychology have since been subjected, and the published results of these exercises are among the most tedious controversies in the history of science. But the possibility of experiment and measurement in psychology was established—paradoxically, by a metaphysical mystic. The metaphysics and the mysticism were soon forgotten, but the exercises live on.

Beneke. Friedrich Eduard Beneke (1798–1854), a contemporary of Herbart, was another philosopher who contributed to the foundation of a science of empirical psychology, which, he claimed, was the basis of all philosophy. Like Herbart, he set out to provide a basis for psychology other than that of a doctrine of faculties, and like Herbart, he stressed the activity of the mind. Among his works on psychology are *Lehrbuch der Psychologie* (1832) and *Die neue Psychologie* (1845). Because of his rejection of the prevailing Hegelian philosophy of the Absolute, Beneke was dismissed from his post in the University of Berlin, but after Hegel's death he was reinstated. His best-known contribution to psychological theory was his doctrine of mental, as contrasted with physiological, traces for the explanation of the facts of memory. This doctrine was later to be developed in Great Britain by Stout.

Müller. Johannes Müller (1801–1858) was a contemporary of Beneke at Berlin. He was the first to hold the title of professor of physiology. (Hitherto, the subject had been taught as a branch of medicine.) He had been under the influence of the prevailing philosophy of nature but contributed to the clarification of the concepts of mind, body, and nature by distinguishing the mental principle, which is restricted in its operation to the nervous system, from the vital principle, which is diffused throughout the organism. He was also preoccupied with the opposition between nativistic and empiricist explanations of space perception as represented, respectively, in the doctrines of Kant and Herbart. Müller reformulated the issue in terms that made it possible to submit the question to experimental tests. He also formulated the theory of specific energies in the nervous system—the hypothesis that the sensory qualities are generated by specific activities of the organs of sense or by specific differentiation in corresponding realities in the brain.

Helmholtz. Hermann von Helmholtz (1821–1894), Müller's distinguished pupil, is acknowledged to be the most outstanding of the physicist-physiologists who have contributed to the development of experimental psychology. In the range of his pioneering studies he has been compared with Francis Galton. His publications were more numerous than Galton's, and his investigations were carried further. He was the first to make a realistic calculation of the speed of nervous impulses, which are important, among other things, in the study of reaction times. He developed Müller's doctrine of specific energies and Thomas Young's three-color theory of vision.

Helmholtz's *Handbuch der physiologischen Optik*, published in three volumes (1856–1866), remained an authoritative text for many decades, although it was not

translated into English until 1924–1925. No less outstanding were his contributions to the theory of hearing and the related subjects of phonetics and music. He was essentially a scientist with little interest in philosophy and still less patience with transcendentalism. There is, however, much in his writings of philosophical interest—for example, his puzzling concept of unconscious inference in perceptual judgments. His discussions of the principle of the conservation of energy are important in the history and philosophy of science.

Wundt. The last phase in the transition of psychology from a branch of philosophy to psychology as an independent empirical science is conveniently dated as beginning in 1879, when Wilhelm Wundt (1832–1920) established the first psychological laboratory. Wundt's chief claim to a place in the history of philosophy arises from the conceptual system in terms of which he interpreted the experimental data from his own and other laboratories. His philosophy of mind deviated from the simpler forms of atomistic sensationism in that the ultimate elements of mind were, according to him, of two kinds, sensations and feelings. He and his disciples devoted much energy and skill to defining the differences between sensations and feelings and to elucidating his curious tridimensional theory of feeling, but the general program was to analyze experience into its elements, to define the fundamental attributes of these elements, and to formulate the laws in accordance with which these elements are combined. The account leaned heavily on the principle of association but deviated from traditional associationist doctrines in introducing a concept of creative synthesis. This concept was a variant of the concept of apperception and embodied a theory of attention. It had some points in common with J. S. Mill's conception of mental chemistry and in some degree foreshadowed later theories of emergent properties and the doctrine of the Gestalt psychologists that a complex experience is more than the sum of its parts. His most influential work was *Grundzüge der physiologischen Psychologie* (1873). In later years he published two works that contributed to the incursion of psychology into sociology and anthropology.

Ebbinghaus and Külpe. Among other outstanding experimental psychologists were two of Wundt's pupils, Hermann Ebbinghaus (1850–1909) and Oswald Külpe (1862–1915). Wundt's laboratory research had been chiefly concerned with sensation and perception and with relatively simple processes of reaction and association. Ebbinghaus and Külpe extended the experimental

method into the study of the higher and more complex functions of memory and the processes of thinking.

In a monumental work, *Über das Gedächtnis* (1885), Ebbinghaus published the results of what has been described by J. C. Flügel in his *A Hundred Years of Psychology* as “the most brilliant single investigation that has ever been made in experimental psychology.” Ebbinghaus’s outstanding achievement was to extend the experimental method to the “higher thought processes.” He was the first to establish quantitative laws concerning the process of memorization. In 1894 he succeeded Theodor Lipps, a pupil of Wundt’s most widely known for his studies in psychological aesthetics, in the chair of psychology at Breslau. There Ebbinghaus pioneered in the study of intelligence and devised the completion test, which remains an important component of intelligence tests.

Külpe directed the laboratory at Würzburg, which achieved great fame through its investigations of willing and judging. Through the discovery of imageless thoughts these studies contributed both to the breakdown of sensationism and, in consequence of the inconclusive disputes this discovery provoked, to the behaviorist revolt against introspective methods. At Würzburg as at Leipzig confusion arose through the interpretation of experimental data in terms of implicit philosophical concepts and assumptions, and the conclusions drawn have had to wait for review in the light of further clarification of the distinction between empirical psychology and the philosophy of mind.

THE SHIFT TO THE UNITED STATES. In the age of Wundt, psychology was a Germanic science, and Germany was the heart of the empire. Mainly through Wundt’s influence upon those who came to Leipzig from the United States, psychology became an American science with the United States as the new seat of dominance. Among those who studied abroad and then returned to America were Stanley Hall, who established the first American psychological laboratory at Johns Hopkins in 1888; J. McKeen Cattell, who after several years as assistant to Wundt founded the laboratory at Pennsylvania; and Hugo Münsterberg, who, having established a laboratory at Freiburg, was invited by William James to Harvard in 1892. In the same year E. W. Scripture took charge of the laboratory at Yale. By 1897 there were fifteen psychological laboratories in the United States, and by the end of the century there were twenty-six, all based, to begin with, on the laboratory in Leipzig. Most of Wundt’s American pupils, however, were soon to deviate from the

German pattern and to open up approaches characteristically American—allergic to philosophical speculation, distrustful of introspective methods, and much concerned with the practical applications of their science. Hall became famous for his studies of adolescence. Cattell, more influenced by Galton than by Wundt, concentrated on the measurement of individual differences. Münsterberg’s interest turned to applications of psychology to industry and criminology. The mantle of Wundt fell upon E. B. Titchener, an Englishman from Oxford who after his studies at Leipzig went to the United States to develop experimental psychology at Cornell.

THE ESTABLISHED ORDER OF 1900. Wundtian psychology was one important form of and ingredient in what has been called the established order of 1900, against which many revolts were to be mounted. There were, in fact, at least two established orders, one in Britain, represented by Ward and Stout, and the other in the United States, represented by Titchener. These were very different establishments, but they had in common a foundation in some form of body-mind dualism and the acceptance of the facts of consciousness, observed by introspection, as defining the subject matter of psychology.

Ward. James Ward (1843–1925) presented his own system as a sort of synthesis of the too objective thesis of Aristotle’s psychology and the too subjective antithesis of Descartes’s psychology. His basic conceptual framework was doubly tripartite. In his analysis of experience he distinguished the three modes of consciousness—cognition, feeling, and conation; his analysis of each kind of experience referred to a self or ego, an act or mental attitude, and a presentation (a mental object, sensation, or idea). The most interesting features of his system are contained in his detailed analysis of the phases of development from simple sensation to perception and from perception to the construction of a memory thread and an ideational tissue. Though qua psychologist Ward can be treated as a dualist, his background metaphysics was a variant of an idealistic monadology of the Leibnizian type.

Stout. G. F. Stout (1860–1944) developed Ward’s psychology in an individual way, creating an original and independent system. As a psychologist Stout, like Ward, developed a dualistic psychology, but as a philosopher he developed an original theory of mind, body, and nature.

Titchener. E. B. Titchener’s laboratory at Cornell was the temple of the Wundtian form of the established order, and Titchener (1867–1927) was its high priest. Here as elsewhere, however, empirical psychology continued to

be inextricably entangled with philosophy. Titchener's deviations from sensationist and associationist psychology were less fundamental than he himself believed. He was a dualist, and he confessed to a bias in favor of sensationism. He was reductionist in his treatment of conation. He differed from the classical sensationists in accepting feelings as basic elements; he also differed from them in the treatment of the elements as existences, as contrasted with meanings. He sought to explain complex mental states as arising from the synthesis of elements and thus to display the structure of the mind. Accordingly, he is described as a structuralist, as opposed to a functionalist, psychologist. His cardinal tenet, which was to become the major object of attack, was his thoroughgoing proclamation of introspection as *the* distinctive method of psychology. His two most important works were his *Lectures on the Psychology of Feeling and Attention* (1908), a detailed exposition of the thesis that "the system of psychology rests upon a threefold foundation: the doctrine of sensation and image, the elementary doctrine of feeling and the doctrine of attention," and the *Lectures on the Experimental Psychology of the Thought* (1909), an equally thoroughgoing examination of the claims for the discovery of an imageless thought element and a polemic against the doctrine of Franz Brentano and Stout that references to object is the criterion of mind.

REVOLTS AND THE ERA OF THE SCHOOLS. The established order of the United States and the established order of Britain were to become the objects of attack from four directions: (1) The behaviorist attack directed in the main against dualism, the concept of consciousness, and the reliance upon introspection; (2) the attack of the Gestalt psychologists against all forms of psychological atomism; (3) the psychoanalytic attack against the overemphasis on conscious processes and inadequate recognition of the unconscious mind; and (4) the attack of the hormic psychologists, which was directed against the intellectualism of traditional psychology—that is, the overemphasis on cognitive processes and the relative disregard for conation or purposiveness in the explanation of conscious experience and behavior.

In the four revolts the schools were all fighting on more than one front. Each was attacking traditional psychology, and each engaged in polemics with the other revolting schools. Confusion was increased by the fact that within each school there were conflicting factions and by the general failure to distinguish straight empirical issues from issues of philosophy and of linguistic usage.

Behaviorism. The conception of psychology as the study of behavior and as an essentially biological science dates back to Aristotle, but behaviorism as an ideology can be dated precisely. It began in 1914, when J. B. Watson (1878–1958) published *Behavior* while a professor at Johns Hopkins University.

This book was a protest and a revolt against dualism, the concept of consciousness, and *any* use of the introspective method in psychology. Psychology is to be the study of behavior by objective methods. It was a protest in defense of animal psychology, in which statements about the animal mind and the consciousness of animals must be pure guesswork, and it was a protest against the interminable and inconclusive disputes between introspective psychologists about the differentiation of sensations and feelings, the James-Lange theory of emotion, and imageless thought. It was also an attack on the traditional theory of consciousness in which some sort of mental stuff was thought to be the subject matter of psychology.

In *Behavior* and two other important books, *Psychology from the Standpoint of a Behaviorist* (1919) and *Behaviorism* (1924), Watson developed his distinctive account of all the major topics that constitute psychology. Like the structuralists he set out to exhibit complexes in terms of simple elements, complex responses to situations as derived from simple responses, native and acquired. The analysis of behavior was in terms of stimulus and response (an analysis to be elaborated later by E. C. Tolman in terms of intervening variables). Sensation and perception were described as responses to present stimuli and constellations of stimuli, memory and learning as responses to past stimuli and neural traces, feelings and emotions as types of sensorimotor responses, and thinking as subvocal verbal behavior. Introspection itself was redescribed as verbal behavior. In his system Watson included much that was irrelevant to the major principle—for example, a bias toward explanations in terms of environmental influence and a bias against explanations in terms of heredity. He had a special bias against the concept of purpose, though later behaviorists found no difficulty in assimilating purposive behavior as goal-directedness. His laws of conditioning were the old laws of association transformed into generalizations about bonds between simple reflexes instead of between simple ideas.

Watson's writings were naive and often confused, but his behaviorism sailed on the tides of the time. Behaviorism was inevitable. Watson's behaviorism was fortunate in that it was reinforced by the most important philo-

sophical movements of the period, positivism and physicalism. It was also reinforced by the logicians and the methodologists of the inductive school, who maintained that scientific laws state correlations between observables. Watson accordingly assumed that because mind was unobservable, it could not be discussed or referred to in science. When logicians later began to proclaim that scientific systems were hypothetico-deductive, such behaviorists as Tolman and C. L. Hull conceded the importance of unobservables in the form of intervening variables and hypothetical constructs. This return to the methodology of Galileo made any simple form of behaviorism difficult to maintain. Nevertheless, B. F. Skinner stuck to the old inductive concept of scientific method and proclaimed that his findings involved no theory. Behaviorism was further supported by a number of outstanding experimental psychologists—for example, K. S. Lashley and W. S. Hunter—sympathetic to Watson's approach.

Lashley was primarily a neurophysiologist who as a behaviorist was more sympathetic to the views of the Gestalt psychologists than to those of Watson. He contributed in an important way to the advance of knowledge concerning the localization of the higher functions in the cortex.

Hunter, a distinguished experimental psychologist, rallied to the support of behaviorism through an odd philosophical argument, based on a very naive form of realism, that consciousness or experience is merely a name applied to what other people call the environment. This argument is reminiscent of a characteristic doctrine of Ward and Stout that the subject matter of psychology comprises "the whole choir of heaven and earth" as it appears to the observer, a view later to be defended by the Gestalt psychologists in terms of the behavioral, as contrasted with the geographical, environment—another variant of the view that things as they appear are appropriate objects of psychological science.

As professor of psychology at the University of California, E. C. Tolman (1886–1959) developed an original system of purposive behaviorism that had perhaps much more in common with the psychology of McDougall than it had with the psychology of Watson. Watson was preoccupied with responses to stimuli. Tolman described Watson's behaviorism as molecular, for it was concerned mostly with physiological details; his own he described as molar, for it was concerned with external and integrated behavior and with emergent properties.

Clark L. Hull (1884–1952), professor at Yale, is known for his inventiveness and originality. His contribution to behaviorism reflects his own interest in

methodological studies and the concept of hypothetico-deductive systems. He constructed a miniature system of this type aimed at a rigorous ordering of some of the basic laws of behavior. His deductive dream and his attempt to develop a Galileo-like resolution of behavior into simple externally initiated movements bore a marked similarity to the mechanistic system of Hobbes.

Behaviorism is not strictly an arguable thesis; it is a pronouncement, a policy statement. The traditional psychologist declares, "I propose to study consciousness by introspection"; the behaviorist says, "I do not; I propose to study behavior by objective methods." The issue is almost as simple as that. There are, however, many arguable issues in particular systems of behaviorism. Reasons can be given for and against policy decisions. There are larger philosophical issues that cannot be evaded.

Roughly three types of behaviorism have emerged: a metaphysical type that says that consciousness does not exist; a methodological type which says that consciousness is not amenable to scientific procedures of investigation; and a radical analytic type, defended chiefly by philosophers, according to which mental facts can all be analyzed in terms of behavior and dispositions to behavior. In Watson's behaviorism and in many others these issues are confused. The behaviorists, no less than Titchener, confused questions of empirical fact with questions of philosophical analysis. It is not possible to know what an emotion is by the introspective observation of emotional states. A prior decision has to be made concerning what to observe, what is to count as an emotion. In the same way it is not possible to know what behavior is by the objective observation of behavior. A prior decision has to be taken about what to observe and about what is to count and what is not to count as an example of behavior. For example, before describing a movement of the body like raising an arm as signaling to a friend or testing the direction of the wind, a person must know what the agent had in mind. This inadequate attention to the question of what constitutes behavior was one of the major weaknesses of behaviorism. Behaviorism is no less riddled by interminable and inconclusive disputes than is introspective psychology. Nevertheless, it has contributed very effectively to the advance of psychology as a biological and an experimental science.

Gestalt psychology. The term *Gestalt psychology* applies primarily to a school of psychology pioneered by Max Wertheimer (1880–1943), Kurt Koffka (1886–1941), and Wolfgang Köhler (b. 1887). Their polemic was directed chiefly against the atomism of traditional psychology and of the established order. They opposed the

thesis that perceptual experience is to be explained by a bricks and mortar account of the combining of simple sensations. Their positive thesis was that what is experienced is always organized and consists of wholes which are greater than the sum of their parts. Like all revolutionaries, they exaggerated the difference between their own ideology and traditional doctrine. The fact with which they were concerned had preoccupied philosophers and psychologists from the beginnings of systematic thought. Aristotle's formal cause was a Gestalt concept, and Kant had grappled with the problem in his treatment of the categories; Ward and Stout had grappled with it in their accounts of the development of the perception of space, time, thinghood, and causality, and Mill had seen the problem when he wrote about mental chemistry. Christian von Ehrenfels (1859–1932), an Austrian philosophical psychologist, introduced the concept of form qualities. There were also contemporary psychologists—for example, Charles Spearman and Henry J. Watt—who were concerned with the concepts of Gestalt psychology in their own ways.

The outstanding contribution of the Gestalt psychologists was in the number, the variety, and the ingenuity of their experiments. Wertheimer's elegant experiments on the perception of movement were followed by no less elegant experiments by himself, his colleagues, and his disciples on the principles of organization in perceptual experience. In the earlier phases Gestalt psychology was as intellectualist as traditional psychology in its preoccupation with the cognitive experience of the normal adult human mind. Its interest extended, however, to child psychology in the studies by Koffka and to animal psychology in Köhler's studies of insight and learning in apes. Kurt Lewin (1890–1947) used Gestalt concepts in the study of problems of personality and of human motivation. The Gestalt psychologists were distinguished chiefly by their experimental inquiries, but in their writings there are many pronouncements relevant to the philosophy of mind.

The slogan "The whole is more than the sum of its parts" is a near tautology but a useful tautology. The increasing emphasis placed by Köhler and Lewin on field theory (the theory concerning properties of total fields of activity as contrasted to the properties of isolated units) has also contributed to the philosophy of science in its application to psychology.

The concept of isomorphism (the parallelism between phenomenal experience and neural processes) has given a new slant to the discussion of classical theories concerning the relations of body and mind.

The experimental findings of the Gestalt psychologists have been assimilated into empirical psychology. Its evaluation as a philosophy of nature, life, and mind must take into account not only its historical antecedents but also some less well known but important contemporary theories, such as those, for example, of Spearman and Watt.

Alternatives to Gestalt psychology. Charles Spearman (1863–1945) made two significant contributions to the development of psychology in the early decades of the twentieth century. The first was through the development of statistical methods in psychology. Building on the studies of Galton and Karl Pearson, he elaborated his two-factor theory for the analysis of human abilities. His second notable contribution was an attempt to formulate principles of cognition, which he believed to be as basic to psychology as Newton's laws had been basic to physics. It was an ambitious plan in which three noegenetic principles—the apprehension of experience, the eduction of relations, and the eduction of correlates—were set out as necessary and sufficient for the explanation of all the cognitive operations of the human mind. The principles of the eduction of relations had been anticipated by Brown's concept of relative suggestion, but in its detailed elaboration it covered most of the facts of cognitive experience studied by the Gestalt psychologists.

Henry J. Watt (1879–1925) enters the history of psychology through his experimental studies of judgment and the higher thought process at the Würzburg laboratory. After his return to Britain he spent the rest of his life at the University of Glasgow elaborating a comprehensive theory that was finally presented in his *Sensory Basis and Structure of Knowledge* (1925). It is a paradoxical fact that atomism, against which Gestalt psychology was directed, should have received its most precise and systematic formulation by a psychologist preoccupied with precisely the facts that Gestalt psychologists were concerned with.

Watt offered an ingenious alternative to Gestalt theory made possible by the sharp distinction he drew between sensationism and associationism, whereas Titchener had treated them as equivalent doctrines. Watt agreed that traditional psychology rested upon two postulates—(1) that the elements of mind are sensations and (2) that the compounds are produced by association. He not only accepted the first postulate, but he also refined it with great subtlety. He rejected the second postulate, replacing it with the doctrine that complex cognitive experiences arise through a distinct process of integration—a concept to which he gave a new definition and which he illustrated in great detail. Watt produced an

original account of the facts that had previously been interpreted in terms of Mill's mental chemistry, Wundt's creative synthesis, Spearman's noetic principles of education, and the principles of Gestalt psychology.

The Gestalt psychologists captured the headlines in the journals of psychology. For a time Spearman had a band of disciples, although Watt's book did not have a second edition. Spearman and Watt had the misfortune of attracting disciples who could neither advance their theory nor excite impassioned critics. Thus, both have been forgotten. Both, however, may be classed among the mute inglorious Miltons of psychology whose works may yet attract the attention of future historians of science.

The philosophy of nature, life, and mind of both Spearman and Watt were, though different from each other, both in the tradition of dualism. That of the Gestalt psychologists was rather different—a dualism of physics and phenomenology. A residual doubt remains. There would appear to be no empirical procedure for deciding between the doctrines of the Gestalt psychologists, of Spearman, and of Watt. The case may again be one in which a choice must be made on grounds of terminological convenience.

Psychoanalysis and derivative schools. The most important revolt against traditional psychology at the turn of the twentieth century was that of Freud and his disciples.

Sigmund Freud created an entirely new psychology—psychoanalysis. This is both a technique of psychotherapy and a body of theory providing a rationale for the technique. The theory developed into an overall account of nature, life, and mind. Freud's philosophy of nature was a conventional nineteenth-century mechanistic materialism predisposing him to an equally conventional preference for physiological explanations of the mind. Thus, it is even more remarkable that his most distinctive and revolutionary doctrines assumed the form of hypotheses to which mechanism and physiology are completely irrelevant.

Central in his system of psychology is the concept of the unconscious. Mind is divided into the conscious, the preconscious, and the unconscious. The conscious is the traditional, familiar, introspectable part of the mind—introspectable thoughts, feelings, and desires. The preconscious consists of all that is out of mind but which can be brought to mind at will or which readily returns to mind in accordance with the accepted laws of association. The unconscious, on the other hand, consists of ideas and wishes, especially wishes, which can be brought into con-

sciousness only by special techniques, of which psychoanalysis is said to be the most fundamental.

Freud's originality did not consist in the discovery of the unconscious, for others before him had hit on this notion, but in postulating that the mind worked in accordance with two different types of laws—those of the primary processes, which included unconscious processes, and those of the secondary processes of thought. The first were ruled by the pleasure principle, the second by the reality principle. The laws of the primary processes were principles of emotive congruence appropriate to wishes. Freud's great contribution to psychological theory lay in postulating these laws of primary processes to explain such phenomena as hysteria, dreams, parapraxes, and so on which were previously unexplained and among which no one had previously seen any connection.

There are some superficial resemblances between Freud's and Herbart's psychology, but these are only superficial. In Herbart's system the contents of the unconscious were ideas; in Freud's system they were mainly wishes. Herbart was concerned with the movement of ideas between consciousness and Freud's preconscious. He had no clear conception of the unconscious mind in Freud's sense. Herbart's explanation of the movements of ideas were formulated in terms of quasi-mechanical forces, efficient causes, whereas Freud's explanatory principles were, in effect, formulated in terms of a truncated type of teleological concept, the Freudian wish. Similarly, Freud's defense mechanisms—sublimation, projection, reaction formation, and the like—were quite unmechanical mechanisms. They were goal-directed procedures for protecting the conscious mind against the unwelcome wishes and ideas that had been repressed.

From first to last Freud was concerned with mental conflict, the conflict between opposing motives. At the beginning he emphasized the conflict between primitive instinctive impulses, mainly sexual, and the need to conform to the rules and norms of society. The emphasis later shifted to the conflict between the life and death wishes. At first the world was astounded and shocked by Freud's theories about sex, especially by his account of infantile sexuality. So prominent was sex in his system that a Freudian explanation of any form of behavior came to be generally thought of as an explanation by reference to unconscious sexual desires. His generalized concept of sex was that all pleasure is essentially the pleasure of sexual experience, including the satisfaction of defecation (anal eroticism) and the satisfaction of sucking and feeding (oral eroticism), as well as the satisfaction derived

from the genital organs (genital eroticism). This general theory of affective experience makes the thesis of infantile sexuality almost tautological. More significant empirically was the thesis of the universality of the Oedipus complex—the thesis that every male child unconsciously wishes to kill his father and have sexual relations with his mother (female children have an Electra complex—the unconscious wish to replace the mother in her relation to the father). These unconscious desires are obvious sources of the conflicts that issue in neuroses and other forms of aberrant behavior.

In Freud's later writings the emphasis was transferred to the conflict between the life-promoting instincts and the desire for death—Eros and Thanatos. When directed outward, the death wish is a source of violence and destruction; when directed inward, it results in suicidal behavior. The concept of the death wish was, however, further generalized. It covered not only the desire to kill and to be destroyed but also the desire to inflict pain and to suffer pain. Thus the odd phenomena of sadism and masochism are explained. As he often did, Freud attempted to reinforce limited hypotheses by highly general theories. The hypothesis of the death wish was based upon the general theory that in all the processes of nature there is a tendency for animated matter to revert to an inorganic state. Slightly less generalized was the theory that all responses to stimuli by an organism were directed to the removal of the stimulus and are thus consummated in unconsciousness, in sleep or death. These speculations were disturbing to his disciples, who felt an obligation to defend them, since these ideas were all but demonstrably mistaken and on the face of it inconsistent with Freud's more basic hedonistic account of human motivation. They were not at all essential to his general theory.

To this phase of Freud's speculations belongs the doctrine that the total personality is organized on three levels—the id, the ego, and the superego. The id consists of the totality of primitive instinctive impulses, and the ego contains the conscious motives. The concept of the superego is the most interesting and original feature of this hierarchy. Although it was often described as the primitive unconscious conscience, Freud explained it as an introjected image of the parent that continued to issue commands and to administer punishment when those commands were disobeyed. Not a few of Freud's disciples have treated the superego as the source of conscience as traditionally conceived and believe it is the explanation of action that accords with moral principles. This, however, was not Freud's view. He was himself a man of great integrity with very definite ethical principles. These prin-

ciples were not derived from his own superego but are to be explained in terms of the distinction between the pleasure principle and the reality principle. Action in accordance with the pleasure principle is directed to immediate pleasure regardless of consequences; action in accordance with the reality principle is directed to maximizing pleasure in the long run. This may be little more than a terminological variation on traditional hedonism, but as is often the case, terminological innovation can contribute to enlightenment.

By 1950 Freudian theory was the dominating influence in psychology. Neither the technique of psychoanalysis nor the supporting theory has received scientific validation, but no theory of human motivation and no form of psychotherapy can ignore the theories and practice of Freud. Freud himself protested that psychoanalysis does not attempt to explain everything, but in the human and social sciences there is hardly a question to which Freudian theory is quite irrelevant. The theory of the unconscious has been advanced and the techniques of analysis developed by such distinguished disciples as his daughter Anna Freud, Melanie Klein (a specialist in the analysis of children), and many others in Europe and the United States. Theory and techniques have also been developed by many disciples and eclectics. Two of Freud's disciples who deviated from his theories—Alfred Adler and Carl Jung—have had very considerable influence.

Alfred Adler (1870–1937) distinguished his system from psychoanalysis by labeling it individual psychology. Before meeting Freud, he had made a special study of the biological phenomena of compensation for defective bodily organs. After his association with Freud he extended his principles to account for all forms of compensation for inferiority, the “inferiority complex.” In deviating from Freud, he assigned less importance to unconscious motivation and to sexuality.

Carl Gustav Jung (1875–1961) labeled his system analytical psychology. He differed from Freud in assigning a less important place to sexual motives and in his account of the unconscious. Jung regarded the libido as an undifferentiated “life force” which became differentiated into a number of instincts or drives. In his long life Jung developed a number of important but highly controversial theories. He elaborated the controversial and obscure concept of the collective unconscious and a theory of archetypal ideas (which has been confused by some with the Platonic concept of archetypes). Less controversial were the results of his experimental studies of word association and his suggestions regarding personality types. His wide-ranging speculations covered alchemy,

mythology, and the psychology of religion. Students of religion have found in Jung much of what they found absent or uncongenial in the writings of Freud. The opposition between Freudian and Jungian psychology has provided a modern parallel to the classical distinction between the Aristotelians and the Platonists.

Horomic psychology. In the Wundtian system as interpreted by Titchener the elements of mind were sensations and feelings. Conative experience had been eliminated by reductive analysis. Similarly, the concept of conative behavior had no place in Watsonian behaviorism. The concept of conation was not prominent in early Gestalt theory. Before 1950, however, the concept of conative or goal-directed behavior had been restored as a key concept in most systems of psychology. Tolman, the most sophisticated of the self-proclaimed behaviorists, established a new purposive behaviorism, and Lewin steered Gestalt psychology into the study of volitional processes. Throughout, Freudian theory is permeated by the facts of goal-directedness. The most thoroughgoing exponent of a conative psychology was William McDougall (1871–1938).

McDougall had a medical education but devoted himself to research in physiology, making several significant discoveries. An important early publication was his brief *Physiological Psychology* (1905), which contains the germs of his later theories. His most important publication was his *Introduction to Social Psychology* (1908). This title was unfortunate since the book contains the essentials of his general theory of motivation. Central to this theory was the thesis that there is a limited number of prime movers by whose conative force every train of thought and every bodily activity is initiated and sustained. These prime movers were first described as instincts, but the objections that were raised to his extreme deviation from the traditional biological conception of an instinct led McDougall to redescribe them as propensities.

In his detailed elaboration of these “propensities” McDougall developed an account of instinctive behavior originally suggested by William James. Prior to James instinct had been regarded as a biological mechanism producing rigid and stereotyped forms of behavior that were neither learned nor modified by experience. James drew attention to the cognitive emotional and impulsive components in instinctive action. McDougall developed this idea within the framework of the tripartite analysis of conscious experience that he had learned from Stout. Stressing the extent to which instinctive dispositions are modified both on the cognitive (receptive) side and on

the conative (responsive) side, he suggested that the primary instincts are to be defined by reference to the central or affective components, the “primary emotions.” He went on to describe the ways in which instinctive dispositions are modified and the ways in which they are organized into more complex motivating dispositions, the sentiments. A sentiment was conceived of as a system of instinctive disposition organized around an idea. Patriotism, for example, is a complex organization of instincts directed to promoting the welfare of a national group. McDougall’s account of the structure of human personality was similar to that first set out in the famous sermons of Bishop Butler on human nature (1726). With McDougall, as with Butler, the motivating forces in man are organized in a three-tiered hierarchy. At the base are the primary instincts or propensities. At the second level in Butler’s system were certain regulating and controlling principles, such as benevolence and cool self-love, and at the summit was the ultimate controlling principle, which was identified with conscience.

In McDougall’s system the basic instincts are organized into and controlled by the sentiments, which function in a similar way to Butler’s principles of benevolence and cool self-love. Thus, the parental sentiment is an organization of the maternal instinct together with other instincts, and in McDougall’s view it explains all disinterested altruism. The self-regarding sentiment is an organization of the instincts of self-assertion together with others that exercise a similar control over primitive aggressive instincts. It functions in McDougall’s theory in a way similar to Butler’s cool self-love and Freud’s reality principle. At the head of the hierarchy in McDougall’s system as the supreme controlling force is a master sentiment that is an elaborated form of the sentiment of self-regard.

Both Butler’s and McDougall’s accounts of the structure of human personality, of human motivation, and of the basis of volition or self-control have important similarities with, but also important differences from, Freud’s hierarchy of id, ego, and superego. Butler’s analysis had greater philosophical subtlety than McDougall’s, but McDougall’s was developed in much greater detail. The central theses were contained in *Social Psychology*. The details were further elaborated in his later works, such as the *Outline of Psychology* (1923) and the *Outline of Abnormal Psychology* (1926). McDougall was himself surprised, as well as gratified, by the outstanding success of his *Introduction to Social Psychology*. He was to be surprised and disappointed by the reception of what he intended to be his magnum opus, *Body and Mind: A History and*

Defense of Animism (1911). This contained a critical review of the traditional theories of the relations of body and mind in which he eventually decided in favor of interactionism. His general philosophy of nature, life, and mind was that of an orthodox dualist and interactionist. This was later developed into a Leibnizian monadology. The personality of man was conceived as a hierarchy of monads. Every monad is potentially a thinking, striving self, but each differs in degrees of development. At the head of the hierarchy is the supreme monad—the self, which is in command of, and directly or indirectly in communication with, all subordinate monads. The mode of communication was conceived to be telepathic.

McDougall was one of the last of the academic psychologists to attempt a comprehensive system covering all the facts of cognition, feeling, and conation as well as the facts of unconscious motivation. His theories, however, fell out of favor, though not entirely because of specific objections to them. They were outmoded by current trends in both psychology and philosophy. Nevertheless, he exercised a considerable influence on thought and research in motivation theory, not least upon those who differed from him, and he contributed to the reunification of psychology and the biological sciences, which had been separated since Aristotle's day. Indeed, it could be argued that McDougall, like Aristotle, saw that the concept of purpose was both logically irreducible to mechanistic concepts and fundamental for the explanation of human behavior. His mistake was to translate this eminently defensible conceptual doctrine into a genetic doctrine about the origins of behavior. The two do not necessarily go together, for the doctrine that human behavior cannot be explained without recourse to a concept like purpose does not entail the genetic doctrine that men must come into the world equipped with a myriad of built-in purposes.

REACTION AGAINST REACTIONS. The proliferation of schools continued into the 1930s. Carl Murchison's *Psychologies of 1925* was followed by his *Psychologies of 1930*, and at the time no end to such quinquennial volumes could be foreseen. Psychologists, however, began to tire of these battles among the schools, each of which was in revolt against the established order and at war with the others in revolt. There came a revolt against revolt, a reaction against reactions. Robert S. Woodworth (1869–1962), who had written the most influential critical commentary on the schools, *Contemporary Schools of Psychology* (1931), was a leading advocate of a middle-of-the-road psychology. Teaching and practicing psychologists tended to be eclectic; many leaned heavily on one or

another of the schools, and only a few remained uncommitted.

Schools were then replaced by “approaches,” a term that suggests convergence rather than divergence. Approaches, like viewpoints, are complementary. The new situation favored the emergence of groups of psychologists united in discipleship to a single dominating personality. These groups differed from the schools in that a school was created by several outstanding personalities who, though agreeing on certain basic theses, made individual contributions to the system of psychology defended by the school. There have always been groups of the simpler leader-and-disciples type. Before the age of the schools there were philosophical psychologists with their disciples—for example, Brentano and Alexius Meinong on the Continent, Ward and Stout in Great Britain, James in the United States. In the schools themselves there were subgroups composed of a man and his disciples—the Freudians, the Jungians, the Pavlovians, and so on. After the dissolution of the schools new personalities emerged, each with an individual approach or field of specialization; there were psychologists like Piaget at Geneva, Albert Michotte at Louvain, and Tolman and many others in the United States.

RELATION TO PHILOSOPHY. The history of psychology in the twentieth century is a story of the divorce and remarriage of psychology and philosophy. The trouble began when psychologists claimed the status of empirical scientists. At first the philosophers were the more aggressive, deriding the young science as a bogus discipline. The psychologists hit back and made contemptuous remarks about philosophical logic-chopping and armchair psychology. The arguments were charged with emotion, and neither side emerged with great credit. Slowly, some progress was made toward a diagnosis of the situation, a diagnosis that may well provide the basis for a happy reconciliation.

Psychology has always been, and may well always remain, a parasitic discipline. For twenty centuries it was just a branch of philosophy. To gain emancipation, it entered into willing bondage to the established natural sciences. Increasingly it has claimed to be, and has been increasingly accepted as, a biological science. Aristotle's psychology had a biological orientation, and theories of the temperaments have always had a physiological slant. Since Darwin psychologists have attempted to work down to the biological foundations of mental life, and biologists have extended their field of interest upward to include the more complex functions of organisms tradi-

tionally described as mental—perception, learning, problem solving. In the twentieth century psychologists and biologists found a common approach, frame of reference, and interest in such new special studies as ethology, cybernetics, and information theory and a common lack of interest or only a peripheral interest in problems of the philosophy of mind. There have, however, been other developments that have helped to resolve the conflicts between philosophers and psychologists and to clarify the lines of demarcation between work that can properly be done in an armchair and work that must be done on a laboratory stool, in a birdwatcher's blind, or behind a one-way screen.

The behaviorists, in their revolt against Titchener's introspectionism, had taken over quite uncritically Titchener's greatest error. Hegel had attempted to answer questions of empirical fact by a priori reasoning. Titchener made the opposite mistake, supposing that questions of philosophical analysis could be settled by observations made in a laboratory. His mistake is on record; he recalled that in 1888, when first reading James Mill's *Analysis of the Human Mind*, the conviction flashed upon him, "You can test all this for yourself." He thought he could test it by introspection. The *Analysis* of James Mill was an exercise in philosophical analysis that can be carried out in a soft armchair, perhaps more efficiently there than on a hard laboratory stool. The behaviorists also fell victim to the same error in confusing introspection and philosophical analysis, in failing to see that questions of analysis arise not only in regard to introspective reports but also in regard to behavioral concepts—stimulus, response, and behavior itself.

However, behaviorists and other biologically minded psychologists were little disposed to either philosophical speculation or philosophical analysis. They were content, like most biologists, to think of the world, regardless of consistency, *both* in terms of commonsense realism and in terms of the billiard-ball atomism of nineteenth-century physics, thereby following the physicists whenever they revised their theories. Those who had some interest in philosophy followed the prevailing trend in philosophy to some form of phenomenalism.

Reduction of mental concepts. There had been three centuries of philosophical thinking devoted to the elimination of superfluous psychological concepts. At first a mind was thought of as an immaterial substance that, like a material substance, persists through changing states. As a rod of iron passes through states of being hard and soft or black, red, and white in accordance with changes of temperature, so a mind passes through states of joy, sor-

row, and so on in accordance with the success and failure of its endeavors. Descartes had described all modes of consciousness as states of the soul, some of which appear to be states of external bodies, others of which appear to be states of the body in which the soul is embodied, and others that really are, as they appear to be, states of the soul itself. In his new way of ideas Locke redescribed experience in terms of the soul, self, or ego being presented with and attending to objects in the mind that chiefly represent things in the external world. Berkeley pointed out, cogently, that there is no way of comparing these representative ideas with the things they are supposed to represent. There were, he suggested, no reasons for, and there were reasons against, supposing that there are material things to be represented. Exit the material world. Then came Hume, who gave an important negative introspective report. He could not observe this soul, self, or ego to which presentations were said to be presented. Exit the soul.

For a long time attempts were made to defend what Titchener described as an act and content psychology—the doctrine that mind consists in mental contents and acts of willing and attending concerned with these contents (without, however, anyone to perform these acts). Late in the nineteenth century Brentano argued that these acts or attitudes are what is distinctive of mind. G. E. Moore based his refutation of idealism on this thesis by distinguishing in sensation the sensing, which alone is distinctively mental, from the sense datum sensed. But, like Hume, he made another negative introspective report—that the act is diaphanous, unintrospectable. Exit the act, the last claimant to mentality.

This reduction and elimination acquired a temporary finality in Bertrand Russell's neutral monism. Influenced by Moore, Ernst Mach, and William James, he proposed the overall theory that the stuff of which the universe is composed is neutral, not mental or physical. Organized in one way, it issues in the laws of physics; organized in another way, it results in the laws of psychology. Combining these, we have an account of nature. In this long reductive process man first had lost his soul, then his mind, then his consciousness, and finally even his body, which was reduced to a permanent possibility of neutralized sensations.

Linguistic approach. The finality of this form of phenomenalism was short-lived. The conception of philosophy as an inquiry into the ultimate nature of reality was supplanted by the idea that philosophy is the critical analysis of the concepts of science and of common sense. This was in turn replaced by the idea of philosophy as the

study of linguistic usages. Instead of asking what mind is, philosophers set out to disentangle the various uses of the word *mental*, and they became interested in the depth psychologists' uses of new words and of old words in new senses. Philosophers and psychologists began to find a new basis for collaboration. The philosophers clarified concepts; the psychologists attempted to verify by laboratory procedures the hypotheses stated in these concepts.

Not all issues between philosophers and psychologists have been resolved, but there has been notable progress toward a policy of coexistence, and here and there some progress toward cooperation has been made.

PSYCHOLOGY [ADDENDUM]

In the 1950s and 1960s, scientific psychology underwent a major transformation. Behaviorist, Gestalt, and Freudian views were largely superseded by an approach called cognitive psychology, which treats the mind as a kind of information processor analogous to a computer. Cognitive psychology investigates the mental structures and processes that underlie perception, attention, learning, memory, language, inference, and problem solving. The field retains some behaviorist, Gestalt, and Freudian insights, but provides a coherent alternative that has been highly fruitful both experimentally and theoretically.

THE COGNITIVE REVOLUTION

The roots of cognitive psychology lie partly in the limitations of previous theoretical approaches to psychology, particularly behaviorism. Behaviorism attempted to make psychology scientific by avoiding reference to hypothetical mental entities such as thoughts and concepts. It tried to restrict psychology to the use of observed stimuli to predict observed behavioral responses. Behaviorism was fueled in part by a positivist philosophy of science that failed to recognize that explanation in natural science abounds with hypothetical entities such as atoms and genes. By the 1950s it was becoming apparent that stimulus-response relations were inadequate to account for human verbal behavior and even for learning in rats.

The emergence of an alternative explanatory framework came from several sources. One was information theory, developed by Claude Shannon in the 1940s, which inspired psychologists such as George Miller to try to characterize the capacities of the human mind to process information. Miller's 1956 paper, "The Magical Number Seven Plus or Minus Two," reviewed evidence that minds are inherently limited in their ability to hold only a small amount of information but argued that this limitation is surmounted by representations that chunk pieces of information together. Cognitive psychology has largely abandoned the information-theoretic division of information into discrete bits, but the metaphor of information processing remains pervasive.

A second and ultimately more important source of cognitive psychology was the development in the late 1940s and 1950s of the idea of a computer program. Before the advent of computers, philosophers and psychologists who wanted to give a mechanistic account of mind were limited to relatively simple mechanisms such as clockworks and telephone switchboards. Computer

programs consist of representational structures such as numbers, words, and lists, along with algorithmic procedures that transform the structures to produce new ones. In their 1960 book *Plans and the Structure of Behavior*, George Miller, Eugene Galanter, and Karl Pribram compared the plans that control behavioral operations to computer programs. By 1956, Allan Newell and Herbert Simon had already developed a computer program that could simulate human performance on a high-level task, proving logic theorems. Most theories in cognitive psychology operate with the analogy that human thought applies mechanical processes to mental representations, just as computation applies algorithms to defined structures. In the strongest view, thinking is not just *like* computation, it *is* a kind of computation.

The third conceptual source for cognitive psychology was Noam Chomsky's new approach to linguistics, developed in the 1950s as an alternative to the behaviorist approaches of Zelig Harris that then dominated the field. Chomsky incisively criticized the explanatory adequacy of behaviorist accounts of language learning. He proposed an alternative that postulated mental structures such as an innate universal grammar that makes possible the efficient learning of any human language.

Ideas about information, computation, and mental grammars redirected the experimental research that occupies most psychologists much more than do theoretical matters. Investigation shifted from studies of animal behavior to experiments with human subjects concerning such mental operations as visual pattern recognition, memory, verbal learning, and speech perception. In 1967 Ulric Neisser published the new enterprise's first textbook, *Cognitive Psychology*, and the journal of the same title began three years later. Neisser focused on processes for visual and auditory cognition.

TOPICS IN COGNITIVE PSYCHOLOGY

Later textbooks have addressed a broader range of topics, especially learning, memory, attention, perception, problem solving, language, representation, decision making, and deductive and inductive inference. Many experimental results have accumulated concerning these cognitive processes.

Research on perception has investigated how people recognize objects and other structures such as faces. Perceptual recognition involves both bottom-up processing from physical stimuli registered on sensory receptors such as the retina, and top-down processing influenced by high-level beliefs and concepts. Visual imagery has been a lively area of research, with Stephen Kosslyn and

others arguing that evidence supports the view that minds operate with visual as well as verbal representations. The study of attention considers the factors that lead people to focus on and shift their concentration to different aspects of their environment.

Memory researchers distinguish between long-term memory, which permanently stores representations of events and concepts, and working memory, which holds and manipulates information as people perform cognitive tasks. Human memory is very different from computer memory, which stores information exactly as presented to it. Consolidation of events and facts into long-term memory involves reconstruction and blending with previous experience. People are conscious of only part of the contents of working memory and are totally unaware of most of the cognitive processing that constitutes thought. Almost all thinking is unconscious, not because of Freudian repression mechanisms, but because people have little access to most of the operations of their brains.

Cognitive psychologists distinguish between episodic memory for particular events and semantic memory for conceptual relationships. Debate has raged concerning what concepts are, although most psychologists reject the traditional view, still found in philosophy, that concepts can be defined by necessary and sufficient conditions. Alternative theories of concepts maintain variously that they consist of prototypes that specify typical but not universal features, sets of exemplars of objects, general knowledge about things, or patterns of activation in neural networks. These theories have inspired experimental investigations of how concepts are learned.

Cognitive psychologists who study language perform experiments concerning how people comprehend and produce utterances. In the 1960s and 1970s, research in psycholinguistics was heavily influenced by Chomsky's theory of transformational grammar, but later research shifted away from emphasis on the syntactic structure of language to concern with its meaning and communicative functions. There has also been investigation of high-level linguistic processes such as reading and understanding discourse.

Like the Gestalt psychologists, cognitive psychologists have been interested in problem solving and creativity. They have constructed detailed computational models of how people solve different kinds of problems using general rules and/or analogies with previous problem solutions. Theories of expertise have been developed based on different accounts of how different mental

structures constitute the knowledge possessed by people with substantial experience in a particular domain.

Psychological investigations of inference have been at odds with normative models of reasoning popular in philosophy. In contrast to the view that deductive inference involves the application of formal syntactic rules such as those found in propositional logic and predicate calculus, much psychological research has supported the view that the human mind makes inferences in a way that does not sharply distinguish syntax from semantics. People make deductive inferences based on the content of representations, not just their form. Similarly, people do not make decisions using the formalism of expected utility theory, which sharply distinguishes utilities from probabilities. Instead, they use a variety of cognitive and emotional heuristics to evaluate and choose different options. It is controversial whether the deviation of people from normative models of inference shows that they are irrational, or whether there is a need for more psychologically realistic models of rationality.

THEORETICAL AND EXPERIMENTAL DEVELOPMENTS

In the 1970s, cognitive psychology became part of the interdisciplinary field of cognitive science, which also includes philosophy, linguistics, anthropology, neuroscience, and the branch of computer science called artificial intelligence. Computational ideas continued to be at the core of psychological theory. Some theorists such as Allen Newell and Herbert Simon, and later John Anderson, maintained that psychological phenomena are best explained by postulating that the mind uses rules of the form, IF such and such, THEN such and such. These rules are operated by procedures that search through a large number of possible sequences of operations to provide solutions to problems. Rule-based models have been used to provide detailed explanations of problem solving, skill acquisition, and language production and acquisition.

Other psychologists have emphasized the role that structures such as concepts and schemas play in cognition. From this perspective, problem solving is not so much a sequential search through a large range of possible moves, as the application of patterns that enable people to comprehend and respond to situations. Thought is viewed as a kind of pattern matching rather than as a search through a space of operators defined by rules. Computational models of visual processing have inspired new theories and experiments concerning the nature of visual imagery.

During the 1980s, there was an influx of theoretical ideas based on computational models of artificial neural networks. This approach is called *connectionism* because it emphasizes the connections (links) between simple neuron-like processors. Inferences of the sort performed by rules and concepts are supposed to emerge from the interactions of many highly connected units that take in activation from many other units and pass it on to many others. Learning consists in adjusting the strengths of the links between the units. Connectionist models have been applied to many psychological phenomena, including learning from examples and high-level problem solving of the sort discussed by Gestalt psychologists.

From psychology journals such as *Cognitive Psychology*, it is evident that most psychological research is experimental rather than theoretical. Experimenters use a variety of measures such as error rates and reaction times to detect characteristics of human thinking. For example, investigations of eyewitness memory and testimony show that it is sometimes inaccurate, with errors being more likely if the witness has been distracted, if the misinformation is plausible, if there is social pressure, and if eyewitnesses have been given surreptitious positive feedback. Studies of deductive and inductive inference look at the difference between examples where people reason well and examples where they tend to make mistakes. Another experimental measure is reaction time, which compares how fast people are to respond to different stimuli. For example, people are quicker to respond to an item if it is preceded by a similar item that primes it.

In the 1990s, cognitive psychology began to draw much closer to neuroscience. Cognitive psychologists have always assumed that mental operations are carried out by the brain, but for decades they lacked experimental techniques to relate human behavior to brain processes. Instruments are now available for imaging what is happening in the brain while people perform cognitive tasks. The most commonly used are PET (positron emission tomography) and fMRI (functional magnetic resonance imaging) scans. Both tools can detect the increase in blood flow to regions of the brain that become active when it is performing a particular task. For example, brain scans can determine what parts of the brain have increased activity when people are asked to rotate mental images. Many cognitive psychologists have turned to performing experiments in which people perform mental tasks while their brains are being scanned.

These experiments have furnished data that are used to suggest and evaluate theories about what brain processes are involved in various cognitive tasks. Increas-

ingly, cognitive theorizing is more brain-oriented, invoking processes that occur within particular brain regions and involve the interactions of multiple brain regions. In contrast to the connectionist models of the 1980s, computational models based on cognitive neuroscience employ much more neurologically realistic ideas about the structure of brain networks and the operation of individual neurons. Whereas cognitive psychology originally ignored the role of motivation and emotion in human thinking, cognitive neuroscience has inspired new models that integrate cognition and emotion in accounts of human decision making. Even the topic of consciousness, assailed by the behaviorists as inherently unscientific, is now being investigated by means of psychological and neurological experiments along with neurocomputational theories.

Cognitive psychologists disagree about the extent to which mental structures and processes are innate. Psycholinguists and evolutionary psychologists such as Stephen Pinker argue that natural selection has furnished the mind with many special purposed inference mechanisms such as a language acquisition device. The alternative view is not that the mind is a blank slate with no innate machinery, but rather that what all humans inherit is a highly flexible learning mechanism that makes possible adaptation to many situations. Although proponents of innateness are more likely to advocate rule-based rather than connectionist theories, there is no inconsistency in maintaining that most rules are learned and that some connections are innate.

OTHER AREAS OF PSYCHOLOGICAL RESEARCH

Cognitive psychology is only one area of psychological research, but it has had a major impact on other areas such as developmental, social, organizational, educational, and clinical psychology. Developmental psychologists study the origins and growth of children's knowledge of language and the world. The ideas of Jean Piaget dominated developmental psychology for decades, but they have been reassessed and revised by means of theories and experiments suggested by cognitive psychology. Developmental psychologists have also constructed new experimental techniques, such as the measurement of infants' attention times used to indicate what kinds of objects and situations are unfamiliar to them.

Social psychology, which concerns how people interact with each other, has become dominated by the field of social cognition, which examines people's cognitive processes. Social cognition investigates how people make

sense of each other using concepts, stereotypes, rules, hypotheses, memories, emotions, personality traits, and other mental representations. Social psychology also looks at how cognition can vary across different cultures. Cognitive psychology has had an equally major impact on organizational psychology, which studies such topics as management and industrial development. In particular, work on organizations has been influenced by cognitive theories of decision making and learning. Similarly, cognitive theories of learning such as ones concerned with the acquisition of rules and concepts have had a substantial impact on educational psychology.

Clinical psychology, another area with practical applications, has also been transformed by the cognitive revolution. This area was once dominated by Freudian theories, which generated little success in either experimental or clinical settings. Cognitive therapy is one of the few kinds of psychotherapy that have been shown in controlled experiments to benefit people with emotional disorders such as depression. Unlike psychoanalysis, it does not require detailed discussion of a patient's childhood, but instead concentrates on helping the patient to replace unrealistic beliefs and goals in order to produce more positive appraisals of themselves and their situations. The medical field of psychiatry has also abandoned Freudian theories in favor of neurochemical explanations and treatments of mental illnesses such as depression, mania, dementia, and schizophrenia.

CONTROVERSIES

Although psychology has accumulated an impressive body of experimental findings and theoretical explanations, there remain topics of controversy that indicate directions of future work and generate interesting philosophical issues. These topics include: nature versus nurture, culture versus universality, rules versus connections, images versus propositions, mental logic versus mental models, heuristics and biases versus the adaptive toolbox, and embodiment versus computation.

NATURE VERSUS NURTURE. Psychologists disagree about the extent to which the behavior of humans is the result of innate, genetically transmitted neural structures (nature), compared with the extent to which it is the result of learning from physical and social environments (nurture). The nature side is currently emphasized by evolutionary psychologists such as Stephen Pinker and Leda Cosmides, who argue that many specific mental abilities have developed as the result of evolution by natural selection. They have proposed that the brain con-

tains evolved modules that are specialized in function, such as a face recognition system, a language acquisition device, navigation specializations, and a routine for detecting cheaters in social situations. The alternative view is not that there are no genetically inherited structures in the brain, but rather that the main innate endowment is a flexible learning ability that enables people to adapt to a wide range of environments. Proponents of this view include Jeffrey Elman, Steven Quartz, and Terrence Sejnowski. Psychologists also debate the extent to which general intelligence is inherited, and even whether there is such a thing in contrast to specific kinds of intelligence such as verbal, social, and physical abilities. Resolution of these debates will require further research on the structure and development of the brain.

UNIVERSALITY VERSUS CULTURE. Psychologists have tended to assume that the mental processes they investigate are universal, operating in all human minds. In contrast, anthropologists have tended to emphasize the diversity of different cultures with respect to beliefs and practices. An increasing number of psychologists have been using experimental methods to investigate the impact of culture on cognition, motivation, and emotion. Richard Nisbett and others have explored the impact of cultural differences on aggressive behavior and even on general styles of thinking. Compared to Westerners, East Asians are more likely to notice environments and relations rather than objects, to see change rather than stability, and to explain other people's behavior in terms of situations and relationships rather than personality traits. This issue is not the same as the nature versus nurture issue because there is no evidence of any relevant biological differences between Westerners and East Asians; cognitive differences therefore reflect culture rather than genetics. Further cross-cultural work in cognitive and social psychology will provide more information on the extent to which cognitive processes are universal.

RULES VERSUS CONNECTIONS. Many psychologists follow Chomsky in supposing that the acquisition and use of language depends on the possession of rules. For example, the standard way to form the past tense in English is to add "ed," as in "Sheila argued with Tom." But there are also many exceptions to this rule, such as "threw" and "went." James McClelland and other connectionists have argued that language use does not require rule acquisition and can be understood as the result of learning mechanisms that modify the links in neural networks. In contrast, Stephen Pinker and others argue that rules are necessary to explain patterns of linguistic behavior.

IMAGES VERSUS PROPOSITIONS. Philosophers such as Jerry Fodor have interpreted the computational view of mind to imply the existence of a language of thought that uses a representational scheme akin to verbal propositions. In contrast, most psychologists maintain that human thinking involves more than one kind of code, in particular visual images in addition to verbal propositions. Stephen Kosslyn and other have argued that a combination of psychological and neurological evidence, along with computer simulations, support the hypothesis that minds use visual as well as verbal representations. For example, brain scanning experiments show that when people perform imaging tasks, they use parts of the brain involved in visual processing. However, Zenon Pylyshyn continues to maintain that the evidence does not support the hypothesis that visual imagery is computationally different from verbal inference.

MENTAL LOGIC VERSUS MENTAL MODELS. How do people perform inferences such as the following? All humans think; anything that thinks has a brain; so all humans have brains. Philosophers since Aristotle have used formal logic to identify valid deductive inferences that accord with rules of inference such as *modus ponens*. Some psychologists such as Lance Rips similarly argue that human inference uses a kind of mental logic based on abstract rules. In contrast, Philip Johnson-Laird and others have presented experimental evidence that human inference does not distinguish form and content, but rather works with concrete instantiations that he calls *mental models*. The mental model approach has been applied to syllogistic, propositional, probabilistic, and causal inferences.

HEURISTICS AND BIASES VERSUS THE ADAPTIVE TOOLBOX. Many philosophers since Aristotle have assumed that humans are inherently rational, but many psychologists have investigated common tendencies to make inferential errors in inductive reasoning. Daniel Kahneman and Amos Tversky launched a fertile research program that showed that people often have difficulty making inferences that accord with normative models based on mathematical theories of probability and utility. They proposed instead that people operate with simple mental heuristics that bias them into making inferential errors. For example, people might think there are more words that start with "R" than end with "R," because it is easier to think of examples of the former rather the latter. Gerd Gigerenzer agrees with Kahneman and Tversky that human rationality is bounded by cognitive limitations but argues that biological evolution has provided people

with heuristics that are fast, frugal, and quite effective. For example, he thinks that people have heuristics for reasoning about frequencies that can enable them to avoid many of the reasoning errors identified by Kahneman and Tversky.

EMBODIMENT VERSUS COMPUTATION. Since the cognitive revolution in the 1960s, most psychologists have adopted the view of mind as an information processor analogous to a computer. An alternative view, based on the work of James Gibson and others, is that much of human behavior can be understood in terms of responses by minds to properties of their physical and social environments. On this view, human thought depends heavily on the kinds of bodies that people have, with sensory and kinesthetic abilities that shape our perceptions and thoughts. Extreme versions of this view deny that computation is part of human thinking at all, but more moderate views emphasize special kinds of computations performed by brains that store information using visual and other formats that are tied to the sensory apparatus of human bodies. Then the embodied nature of much of human thinking is a useful supplement to the computational theory of mind, not an alternative to it.

RELATIONS TO PHILOSOPHY

Developments in cognitive psychology have been important to philosophy for two reasons. First, philosophy of mind has responded to changes in the nature of psychological theories and explanations, with implications for metaphysical issues concerning the relation of mind and body. Second, a major strain of epistemology has become naturalistic, viewing theories of knowledge as continuous with cognitive psychology. Philosophical naturalism has also had an impact on ethics.

PHILOSOPHY OF MIND AND PSYCHOLOGY. The common-sense theory of mind is dualism, according to which people consist of two substances, matter and soul. In contrast, materialism maintains that humans, like the rest of the universe, consist only of matter and energy. Materialists from Epicurus to Lucretius to Thomas Hobbes have faced the daunting project of explaining how mental phenomena such as thinking and consciousness arise from brain activity. The development of cognitive psychology, with its view of thinking as computation performed by the brain, has greatly contributed to philosophical theories of mind.

In the 1960s and 1970s, philosophers such as Hilary Putnam, Jerry Fodor, and Daniel Dennett discussed the

implications of the new ideas about computation and cognition. In the 1950s, materialist philosophers such as J. J. Smart had advocated an *identity* theory, according to which mental processes are brain processes. But the advent of artificial intelligence and computational theories of mind suggested an alternative view that mental processes are independent of any particular physical realization. This view is called *functionalism* because it understands mental states as functional states that are related to each other computationally. Functionalism is still a version of materialism, because it assumes that mental states have a basis in brains, computers, or some other form of matter and energy. But it differs from the identity theory in not equating mental states with any particular kind of physical state.

Functionalism gained much plausibility from the rise of computational views of mind, but it has been challenged by developments in cognitive neuroscience. Cognitive psychology has moved away from abstract computational theories toward theories embedded in particular accounts of the structure and processes in the human brain. It has therefore become less plausible that mental states are functional states rather than specific brain states. Moreover, progress in the field of artificial intelligence has not been as great as its originators had hoped. There have been some impressive industrial applications, but the prospect of a general-purpose machine intelligence comparable to humans remains distant. In contrast, understanding of how the brain uses the biochemical properties of neurons organized into connected functional areas has expanded rapidly. Hence developments in scientific psychology have lent support to identity over functionalist theories of mind. Some philosophers such as David Chalmers have argued that problems in understanding consciousness require a form of dualism, but many psychologists and neuroscientists remain optimistic that even consciousness will yield to scientific explanation.

What is the nature of the theories, explanations, and experimental results that cognitive psychologists offer? Philosophy of science has often adopted the model, derived from physics, that a theory consists of universal laws that deductively explain universal generalizations from observation. But the results of psychological experiments are usually statistically significant effects or tendencies, not laws. Moreover, psychological theories are rarely stated as universal laws, and the relationship between theories and what they explain is rarely deductive. Instead, a theory in cognitive psychology is a description of a computational or neurological mechanism,

where a mechanism is a system of parts whose properties and relations produce regular changes in other parts. For example, a bicycle is a mechanism consisting of parts such as pedals, wheels, a crank, and a chain that interact with each other. In purely computational theories such as those based on rules, the parts are mental representations, and the changes are brought about by computations on the representations. In neurological theories, the parts are neurons organized into brain areas and the changes are brought about by biochemical processes. Ideally, theories can be both neurological and computational when they show how groups of neurons implement mental representations and how biochemical processes implement computational operations.

PHILOSOPHICAL NATURALISM. Naturalism is the view that philosophical problems are continuous with those in science and amenable to treatment by the same kinds of methods used by scientists, as opposed to a priori theorizing about necessary truths and nonnatural entities such as gods and souls. In the late twentieth century, naturalized epistemology was revived through the work of philosophers such as Willard Van Orman Quine and Alvin Goldman. Quine's naturalism was limited by his adherence to behaviorist psychology, but later work has made full use of the expanding resources of cognitive psychology. Goldman has shown how to link philosophical questions about the origins and justification of knowledge with psychological research on perception, memory, and inference. This kind of naturalism does not use psychology to replace or reduce philosophy, which remains concerned with normative issues about justification that are not studied by psychologists. But naturalism applies epistemic appraisal to psychological processes that operate in human brains. Epistemic naturalism has also influenced the philosophy of science, with the view that scientific theories are mental structures rather than logical entities.

Moral naturalism has also been revived by philosophers who argue that ethics needs to pay close attention to cognitive psychology and neuroscience. According to moral naturalists such as Owen Flanagan, construction of moral theories and projection of moral ideals needs to ensure that the character, decision making, and behavior prescribed are possible for human beings. Understanding and evaluation of moral judgments is improved by appreciating how they arise from cognitive and neural processes such as concept application and empathy, which requires integration of cognitive operations with emotional processes. As with naturalized epistemology, moral naturalism does not purport to reduce ethics to

psychology, but rather to develop a richer account of moral justification consistent with rapidly increasing scientific knowledge about the cognitive and neurological sources of human action and judgment. Similarly, some philosophers have become involved in controversies concerning human rationality that arise from the debates about mental logic and heuristics and biases. According to the naturalistic perspective, epistemology, ethics, and metaphysics should continue to evolve hand in hand with further developments in cognitive psychology and neuroscience.

PSYCHOLOGY, GESTALT

See *Gestalt Theory*

PUFENDORF, SAMUEL VON (1632–1694)

Samuel von Pufendorf, the German political and legal philosopher and historian, was born in Dorfchemnitz, in Meissen, Saxony, the son of a poor Lutheran pastor. A scholarship enabled Pufendorf to attend the famous Prince's School at Grimma. From 1650 to 1656 he attended lectures on Lutheran theology and Aristotelian philosophy at Leipzig. Somewhat later he studied contemporary philosophy at Jena, where he also read newly published books on mathematics and discovered the works of Hugo Grotius and Thomas Hobbes. At Jena he came in contact with Erhard Weigel, a former teacher of Gottfried Wilhelm Leibniz, whose strange but original method of teaching ethics "mathematically" made a lasting impression upon Pufendorf. To Weigel, Pufendorf owed the inspiration for his first work on the general

principles of law, *Elementorum Jurisprudentiae Universalis*. In 1658 Pufendorf became a tutor in the house of the Swedish ambassador to Denmark. When war broke out between Sweden and Denmark, Pufendorf was imprisoned for eight months, and it was during this imprisonment that he composed the booklet inspired by Weigel. Upon his release Pufendorf migrated in 1659 to the Netherlands, where the work was published in 1660.

On the recommendation of Grotius's elder son, Pufendorf was offered the chair of natural and international law at Heidelberg, the first such chair at a German university. He was soon appointed also as instructor of the heir to the crown of the Palatinate, and thus he began to mix with the electoral court, where he avidly studied the burning contemporary political problems. Out of this study came a pseudonymous work on the condition of the Holy Roman Empire, *De Statu Imperii Germanici* (1667), a work later famous for its statement that the constitution of the Empire resembles a monster, being neither a monarchy nor an aristocracy nor a democracy.

After his appointment as professor of natural law at the University of Lund in Sweden, Pufendorf wrote his fundamental work on national and international law, *De Jure Naturae et Gentium* (1672). The eight volumes of this compendium, which contains a veritable encyclopedia of the social sciences, are rather difficult reading. Pufendorf therefore produced an abstract of this work, titled *De Officio Hominis et Civis* (1673), which was soon translated into English, French, and German and thus found many readers abroad. By 1684 a Swiss Calvinist theologian was lecturing on the *De Officio Hominis* at Lausanne, but Lutheran theologians in both Sweden and Germany criticized Pufendorf's ideas vehemently. The king of Sweden himself had to protect his professor of law and induce the authorities of the university to defend Pufendorf against the charge of heresy. Pufendorf replied bitterly to the charge, and a long paper war ensued. Finally, Pufendorf published a "sanguinary" (his own description) polemical treatise titled *Eris Scandica* (Frankfurt, 1686), containing all his essays and letters relating to the controversy.

In 1677 Pufendorf was appointed by the king as court historian in Stockholm, where he spent ten years working on his extensive, thirty-three-volume history of Sweden, a work of no importance today except as an example of careful work and precise reporting. His shorter *Einleitung zu der Historie der vornehmster Reiche und Staaten* (2 vols., Frankfurt, 1682–1685) is more highly esteemed.

From 1688 until his death shortly after having been knighted by his former sovereign, the king of Sweden, Pufendorf lived in Berlin, where he had been called as court historian by the elector of Brandenburg.

A noted representative of the Baroque era, Pufendorf was a man of great self-confidence and stolid self-reliance. He had unshakable faith in the power of scientific reason and wished to establish it in the fields of jurisprudence and politics. He believed in the certainty of mathematics and rejoiced in the reunion of philosophy and mathematics then taking place. Although he wished to treat the problematic questions of jurisprudence and politics “mathematically,” he was a true empiricist who sought to introduce a “scientific” method into the study of history. He was therefore eager to undertake the thoroughly planned research into public archives that resulted in his history of Sweden.

Pufendorf thus united the two major trends of his age, Baconian empiricism and Cartesian logicism. One of the last polyhistorians, he united in his work all the methods of historical, sociological, and juridical thinking. A political figure rather than simply a lawyer, Pufendorf profoundly criticized the constitution of the Holy Roman Empire and its political conception. He argued for the founding of a European federation of sovereign states. He did not defend national or regional absolutism, however popular they were at the time; instead, he tried to unite the Hobbesian doctrine that the state should be governed by the rule of law and based on natural law in the empirical sense of the term (the war of all against all, *status necessitatis*) with the Grotian doctrine that the rule of international law should be based on natural law in an emotional sense (an inclination for society, *ordo amoris*). On this account Pufendorf has often been called a predecessor of eighteenth-century rationalism. Such a view is supported by his letter to his younger friend Christian Thomasius, in which he claimed that he “never had boldness enough to draw the utmost conclusions” from his philosophical rationalism and voluntarism.

Despite Leibniz’s opinion that Pufendorf was “a man of no great judgment,” his legal thought was of considerable importance and great philosophical interest. He was undoubtedly one of the most outstanding social philosophers on the European continent in the seventeenth century. It may be an exaggeration to call Pufendorf the first “philosopher of culture” (*Kulturphilosoph*) in Germany, but he was the first to grasp the fundamental concept of the sociological theory of law and politics. He saw the social realities of human life as a whole. His structural distinction between physical facts and moral institutions

inspired a new way of studying social facts in their independence and uniqueness. Following Weigel, Pufendorf distinguished four elements of social being: personality (*persona*), rank or profession (*status*), quality, and quantity. Every pattern of social order should be examined on the basis of these fundamental structures; for example, a state may be described in terms of its sovereignty, type of government, power, and population.

These elements, the ontological foundations of every community, have simultaneously to be interpreted as fundamental ethical principles of social life. Pufendorf designated three patterns of well-formed communities: humanity, ordered by the law of reason; Christianity, ordered by the law of God; and citizenship, ordered by the law of the state. Natural law, including religious and rational principles, therefore limits both civic and moral duties. Philosophy of law comprises both sociology and political science on the one hand, and jurisprudence and ethics on the other. This new discipline, which Pufendorf called simply natural law, was intended to unite all the tasks of interpreting social order and to combine the scholastic methods of the sixteenth-century Spanish thinkers with the newer ideas of Grotius and Hobbes.

In apparent contradiction to these sources of his thought on social order was Pufendorf’s strong belief in reason of state (*ratio status*). Although he often emphasized the self-determination and self-sufficiency of the state, he did not mean by this a totalitarian absolutism. And although he proclaimed the independence of political power against every ecclesiastical claim, he never taught the modern ideology of unlimited government, and his views were therefore not contradictory to the rule of law. What Pufendorf said about the relation of church and state must be interpreted dialectically. He conceded neither decisive authority to reason of state nor the right of moral constraint to the church.

Pufendorf may be called the initiator of the seventeenth-century movement of “scientific” natural law in Germany. By introducing the ideas of Grotius and Hobbes into German thought he made their ideas really effective for the first time. He liberated the natural-law theory from the domination of scholasticism and humanism. In so doing he built up an independent political science that always took into account contemporary history and reason of state. A clever and levelheaded politician, he predicted the decline of the Hapsburg monarchy after the Treaty of Westphalia. In criticizing the “monstrous” constitution of the empire he sought to advance a European commonwealth based on the natural and rational principles of international law. As a histo-

rian, Pufendorf introduced the empirical study of archives and gave an effective example of a new method of historical insight, and he may be regarded as an important predecessor of nineteenth-century historicism.

PUNISHMENT

The word *punishment* is used in varying contexts. The punishment meted out by the state to a criminal or by a parent to his children is not the same as the punishment boxers give or receive. The latter, however, is punishment only in a metaphorical sense, for it lacks several of the features necessary to a standard case of punishment. Characteristically, punishment is unpleasant. It is inflicted on an offender because of an offense he has committed; it is deliberately imposed, not just the natural consequence of a person's action (like a hangover), and the unpleasantness is essential to it, not an accidental accompaniment to some other treatment (like the pain of the dentist's drill). It is imposed by an agent authorized by the system of rules against which an offense has been committed; a lynching is not a standard case of punishment. Philosophers who have written on punishment have usually had in mind punishment in the standard sense rather than in any extended or metaphorical sense.

The philosopher's interest in punishment is mainly connected with questions of justification. It is, *prima facie*, wrong to deliberately inflict suffering or deprivation on another person, yet punishment consists in doing precisely this. What conditions, the philosopher asks, would justify it? Or, more generally, what kind of consideration would count toward a justification? For instance, if a person had already committed a crime, that would clearly be relevant to the question of whether he ought to be punished (although it might not be conclusive). What if he were only expected to commit a crime in the future? Or, again, is it relevant to the question of whether this man should be punished to say that punishing him would deter others? And assuming that criminals ought to be punished, how should we set about deciding appropriate penalties?

It is not, of course, the business of the moral or social philosopher to provide a justification for any particular act or system of punishment or even of the institution of punishment in general. Philosophers are not necessarily apologists for their society and age. They are interested in the procedures and modes of argument that we are committed to by our fundamental conceptions of morality and in criteria of criticism and justification rather than in inquiries into whether actual institutions satisfy them.

Philosophers, it is true, have not always made this distinction; they have often worked on the understanding that a philosophical argument could be seriously shaken by showing that it leads to conclusions inconsistent with some widely approved institution or moral rule. More-

over, for many philosophers, if such a rule or institution seemed to imply a principle inconsistent with other moral principles accepted by the society, there must necessarily be some broader principle, which a philosopher could discover and by which the conflict could be resolved. Applied to the case of punishment, this would mean that a philosopher must reconcile the apparently conflicting principles that wrongdoers should be punished and that it is wrong to deliberately make another person suffer. But this is surely a misconception of the nature of philosophy. There is no point, after all, in asking whether and how punishment can be justified if one assumed in advance that it can. For justification a number of contingent facts are required that the philosopher as such is not qualified to provide. His task is to analyze what is being asked for and so to point out what kinds of facts and arguments are admissible to the discussion.

JUSTIFICATION OF PUNISHMENT

The question of justification arises at two levels. One can take for granted the principle that wrongdoers should be punished and ask whether a particular case of punishment was justified. At this level the philosopher is concerned with the criteria in a general system which any particular act of punishment must satisfy. One can, however, question the very idea of punishment as an institution that involves deliberately inflicting pain or deprivation. This raises the philosophical question of how one justifies a set of rules or an institution like a penal system. Corresponding to these two levels of justification are two broadly opposed approaches to punishment, the retributivist and the utilitarian. Each, in fact, has been taken to offer an answer to the problems at both levels, but the persuasive force of retributivism is mainly in its answers to problems of the first type, and of utilitarianism to questions of the second type. Characteristically, the retributivist stresses guilt and desert, looking back to the crime to justify punishment and denying that the consequences of punishment, beneficial or otherwise, have any relevance to justification. The utilitarian, on the other hand, insists that punishment can be justified only if it has beneficent consequences that outweigh the intrinsic evil of inflicting suffering on human beings.

RETRIBUTIVIST THEORIES. The most thoroughgoing retributivists, exemplified by Immanuel Kant, maintain that the punishment of crime is right in itself, that it is fitting that the guilty should suffer, and that justice, or the moral order, requires the institution of punishment. This, however, is not to justify punishment but, rather, to deny that it needs any justification. To say that something is

right or good in itself means that it does not need to be justified in terms of the value or rightness of anything else. Its intrinsic value is appreciated immediately or intuitively. But since at least some people do doubt that punishment is right, an appeal to intuition is necessarily unsatisfactory. Again, to say "it is fitting" or "justice demands" that the guilty should suffer is only to reaffirm that punishment is right, not to give grounds for thinking so.

Some retributivists, while admitting that punishment is, *prima facie*, evil, maintain that it is nevertheless better that the wicked should be punished than that they should prosper more than the virtuous and, perhaps, at their expense. In this view, the function of criminal law is to punish wickedness or immorality in order to maintain a kind of cosmic distributive justice. However, it is not self-evident that wickedness should be punished any more than it is self-evident that legal guilt should be. Archbishop Temple, himself a retributivist, declared that he had no "intuition that it is good that the wicked should suffer." Nor is it clear that virtue must be rewarded or that universal justice requires the kind of human rectification that this sort of retributivism envisages. Of course, in a universe in which the wicked prospered, there might be no incentive to virtue, but this is essentially a utilitarian mode of argument. Again, evil motives and a bad character are necessary conditions of wickedness but not of legal guilt and criminal liability. The state's function is to punish breaches of those rules which in the public interest ought to be upheld; it is a matter of indifference in law (but not in morals) that some men who observe the rules do so from the unworthy motive of fear and others break them from laudable motives of principle. Conversely, it is at least doubtful whether the criminal law should provide penalties for offenses against morality except where the public interest is at stake—for example, whether it should extend to cases of lying other than, say, false pretenses and perjury.

Though immorality is neither a necessary nor a sufficient condition for punishment, the relation between law and morals is nevertheless a close one, and what punishment is to the one, blame is to the other. Both regulate social intercourse, and in any given society the aims and ideals upheld by the law will usually correspond, more or less, with those upheld by the dominant morality. Moreover, in the family and the school punishment is often used to reinforce moral condemnation as part of the process of moral education. Some writers who regard punishment as moral retribution couple this idea with the argument that the point of punishment is to be found

in what Lord Justice Denning has called “the emphatic denunciation by the community of a crime.” In this view, punishment reinforces the community’s respect for its legal and moral standards, which criminal acts would tend to undermine if they were not solemnly denounced. There is, however, no intrinsic reason why denunciation should take precisely the form of inflicting suffering on criminals, unless, perhaps, one accepts Ewing’s view that punishment has the advantage of impressing both on the criminal and on everyone else that a breach of law and morals is so serious that society must do something to prevent it. That, however, is surely to justify punishment by its utility in maintaining respect for the law. Hastings Rashdall refers to “the enormous importance of the criminal law in promoting the moral education of the public mind,” but Rashdall was a utilitarian who justified punishment by reference to “the production of good effects on conscious beings.”

For G. W. F. Hegel punishment is necessary to annul the wrong done by the criminal. By this he means something more than restitution or compensation, neither of which is, strictly speaking, punishment. It is, rather, that the criminal has upset the balance of the moral order, which can be restored only by his being made to suffer. Or, in terms of the dialectic, crime is a negation of right and as such a nullity; punishment negates the negation, thus reaffirming the right. But in what sense can punishment be said to restore the balance or annul the wrong, unless it is taken for granted that criminals deserve to be punished? This is precisely the point in question.

UTILITARIAN THEORIES. The utilitarian position is exemplified in Jeremy Bentham’s remark that “all punishment is a mischief.... If it ought at all to be admitted, it ought only to be admitted in as far as it promises to exclude some greater evil.” By reforming the criminal, by deterring him or others from similar offenses in the future, or by directly preventing further offenses by imprisonment, deportation, or execution, the good that comes out of punishment may outweigh (so the utilitarian argues) the intrinsic evil of suffering deliberately inflicted. Without such effects, or if the suffering inflicted exceeded the suffering avoided, the institution would be unjustified.

The critics of utilitarianism claim that if people generally could be persuaded that an innocent man was guilty, utilitarianism would justify punishing him since as a warning to others he would be just as useful as a genuine offender. Again, offenders might be deterred by threatening to punish their wives and children, particu-

larly, if as is so often the case with political terrorists and resistance fighters, it were difficult to catch the offenders themselves. Or, again, if punishment could be justified as a way of reforming criminals, it would seem better to punish them before, rather than after, they committed their crimes. Retributivists claim that utilitarians are in danger of losing sight of two conditions that are necessary to the very idea of punishment—namely, that an offense should have been committed and that punishment shall be of the offender himself, who alone can be said to deserve it. “Punishment is punishment,” wrote F. H. Bradley, “only when it is deserved”; punishment for any other reason is “a crying injustice.”

The dilemma of utilitarianism, then, at least in its crude form, is that it justifies punishing innocent people provided that such punishment causes less suffering than might otherwise be caused by the would-be criminals it deters. Some utilitarians argue that in the end the deception would break down, that it could not be used systematically, or that the long-term consequences would be bad for society. But these answers are unsatisfactory because they depend on assumptions of purely contingent consequences. Our revulsion against punishing innocent people seems to go deeper than that. In any case, these answers will not meet the case for punishing hostages, which can certainly be done systematically and requires no deception or secrecy.

PUNISHMENT AND PRINCIPLES OF JUSTICE. To meet the above criticisms, a crude utilitarianism would have to be supplemented by other moral principles—namely, that differences in treatment must be justified by relevant differences in circumstance or condition, where “relevance” is defined in the light of general rules, and that every human being should be treated with at least a minimum of respect as a source of claims and not as a mere instrument for the promotion of the interests of others. It can be argued that punishment of the innocent or of hostages is an abuse not because it necessarily makes for more unhappiness than it prevents but because it treats innocent men in a way that is appropriate only for the guilty and makes an arbitrary difference in treatment between them and other innocent men. Moreover, a legal system is designed to guide conduct by laying down rules and attaching penalties to those who choose to break them. It is acceptable, in the words of J. D. Mabbott, only because “the criminal makes the essential choice; he ‘brings it on himself.’” Otherwise, punishment would not be consistent with the principle of respect for persons. The hostage, on the other hand, has no chance to settle his own fate; he is used as a mere lever for manipulating

other people's conduct, and his own interest is subordinate to that of the other members of society. Punishment of the innocent ignores, in short, fundamental procedural rules of justice and morality without which utilitarianism would make little sense, for unless everyone is worthy of equal consideration as a source of claims, whose interest is to count in assessing the utility of a course of action? Whom are we entitled to treat as simply a tool for advancing other men's interests—as Aristotle's "slave by nature"—and what would count as a reason for considering other men before him?

This has bearing, too, on the reasons for accepting as excuses such defenses as duress, unavoidable accident, or ignorance of fact—conditions under which an offender can claim that he could not help doing what he did. Bentham argued that to punish anyone under such conditions would be pointless and, therefore, mischievous, because the threat of penalties could not possibly deter anyone in the future who was similarly placed. Now, it is true that nothing would be lost if such people escaped punishment, provided they could be distinguished from cheats trying to take advantage of such excuses and provided enough offenders without such excuses could be detected to furnish examples for others. The principle of "strict liability," which exists in some legal systems for certain offenses, has been defended on the utilitarian ground that it is impossible to tell a genuine excuse from a pretense. It is questionable, however, whether a person who would otherwise be treated as innocent ought to be treated as guilty because someone else might otherwise escape a merited penalty. Punishing the man who commits an offense through ignorance or accident, because it is too difficult to tell whether he really did it on purpose or because we have to make an example of *someone*, is very like punishing the innocent as a warning to the guilty. The utilitarian case for these excuses is unsatisfactory inasmuch as it makes them subject to such qualifications.

A better ground for such excuses is that punishment is morally acceptable only if it is the consequence of an act freely chosen by the criminal, which it would not be under these conditions. A man acting in ignorance or by accident cannot be said to bring his punishment on himself. Punishment, seen as a way of influencing conduct, cannot be justified if there has been no real possibility of choice. Moreover, the punishment of involuntary offenses introduces into men's lives the possibility of disasters that they can neither foresee nor avert.

Utilitarianism, then, must be supplemented by principles of justice if it is not to clash with other moral prin-

ciples that are usually considered fundamental. It has, however, the merit, as an approach to the justification of punishment, that it provides a clear procedure for determining whether the institution is acceptable in general terms. This the retributivist approach cannot do because it denies the relevance of weighing advantages and disadvantages, which is what we ultimately must do in moral criticism of rules and institutions. Consequently, a retributivist justification of punishment as an institution usually turns out to be a denial of the necessity for justification, a veiled reference to the beneficial results of punishment (a utilitarianism in disguise), or an appeal to religious authority.

When it is a question of justifying a particular case of punishment, however, the retributivist is in a far stronger position. There would be no point in having a general rule if on every occasion that it had to be applied one had to consider whether the advantages in this particular case warranted acting in accordance with it. Moreover, the point of punishment as deterrent would be quite lost were there no general expectation, based on the general operation of the rule, that the guilty would be punished. Assuming, then, that a penal system can be justified in utilitarian terms, any offense is at least *prima facie* an occasion for a penalty. Equally, without an offense there is no question of a penalty. The retributivist contention that punishment is justified if, and only if, it is deserved is really applicable, therefore, to the justification of particular instances of punishment, the institution as such being taken for granted.

SEVERITY OF PUNISHMENT

The clash between the utilitarian and retributivist approaches to punishment also arises in considering the criteria by which appropriate punishments are assessed. The retributivist insists that the punishment must fit the crime; the utilitarian relates the penalty to the general aims of the system, to the prevention of further crime, and, perhaps, to the reform of the criminal.

The most extreme form of retributivism is the law of retaliation: "an eye for an eye." This alone, Kant claimed, could provide a just measure of the penalty, since it was the crime itself and nothing else that settled it. However, to try to apply it literally might be monstrously cruel, or, as Kant recognized, it might be absurd. Thieves can be deprived of their property and murderers hanged, but what penalty is appropriate to the dope-peddler, the blackmailer, and the smuggler?

There is not much sense, either, in trying to construct a table of equivalents so that the amount of suffering

inflicted by the criminal could be meted out to him in some other form. How can such a table be drawn up? How many years must a blackmailer spend in jail to experience suffering equal to his victim's? Is it possible, in any case, to make comparisons of suffering between persons? Of course, we do assess the gravity of an offense and try to ensure that the punishment for a trivial offense is less severe than for a serious one. But this is possible only because we take for granted an existing scale of penalties and grade new offenses accordingly. Such grading does not imply an intrinsic relation between the crime and the penalty apart from that established by the scale. Some retributivists admit this but claim nevertheless that the penalties prescribed by the law ought to reflect the moral heinousness of the offense. The most serious offenses against morals deserve the most severe penalties. This, however, only shifts the question a step back, for what makes one moral offense more serious than another?

Utilitarians have tended to concentrate on deterrence, turning away from the actual criminal act except as one of a class of actions that might be prevented by punishing the particular instance severely enough (but only just enough) to make the action unattractive to the offender and to possible future offenders. Unfortunately, there are always people who cannot be deterred or reformed. Beyond a certain point the additional suffering one would have to inflict on all offenders to reduce their number might be so great as to exceed the amount of suffering thereby averted. The aim of the utilitarian, then, would presumably be to select the penalty at which the aggregate of suffering caused by crimes actually committed and punishments actually inflicted would be the smallest possible.

The utilitarian approach has often been criticized as justifying severe penalties for trivial offenses and vice versa. To eliminate parking offenses might need heavier penalties than to eliminate blackmail, which would be monstrous. But this criticism misses the point of the utilitarian case. There would, indeed, be no objection to threatening the severest penalty for any offense providing the threat never had to be carried out. Punishment is only an unfortunate consequence of the fact that the threats, which are the true operative elements in the system, are partially ineffective and would be wholly ineffective if they were not carried out when they failed to deter. In fixing penalties, the utilitarian's problem is not, therefore, to minimize the number of offenses, irrespective of the punishment inflicted, but to minimize the total amount of suffering from both sources. If we call parking offenses trivial, we mean that each one causes relatively little suf-

fering; therefore, we are prepared to put up with a large number of them rather than incur the cost of making offenders suffer heavy penalties. Blackmail, on the other hand, causes so much suffering that if heavier penalties would yield even a small reduction in the number of offenses, there might be a net gain even though offenders would suffer more than they did before. In this way a utilitarian might agree with the retributivist that severe penalties ought to be restricted to serious offenses, but he would argue that we call an offense serious precisely because it causes a great deal of suffering. For the retributivist only serious crimes *deserve* severe penalties; for the utilitarian only serious crimes are worth averting at the cost of severe penalties.

The utilitarian approach to this matter does not supply a procedure for sentencing particular criminals (any more than a justification for punishment as an institution would be a case for any particular application of it). Arguing from expected consequences, one might establish a kind of standard penalty for each class of offense. Officials drafting new rules might consider whether a proposed maximum penalty would keep offenses down to manageable proportions, or people concerned about road accidents might argue that heavier penalties for motoring offenses would make drivers more careful. Deciding the sentence in a particular case, however, is clearly a different matter. The maximum penalty is a limiting factor, but questions like the degree of responsibility, provocation, and the offender's previous record are all relevant. However, one might reasonably ask why, as a matter of principle, they should be relevant.

PUNISHMENT AND RESPONSIBILITY

The problem of responsibility arises in relation to punishment as it does in relation to blame in moral theory. The principle, discussed already, that a man ought not to be punished for doing what he cannot help creates difficulties when extended to actions which a man could not help doing because of his own state of mind instead of external or contingent factors, like duress or ignorance of fact. An insane man, as defined, say, by the M'Naghten rules (that is, one who did not know what he was doing or did not know that what he was doing was wrong), cannot be said to choose his act because he cannot know it for what it is. But sometimes a man may know that what he is doing is wrong yet still be unable to stop himself from doing it. He may be subject, for instance, to an irresistible temptation or provocation. But how is that to be understood? A temptation is not irresistible merely because a particular man has yielded to it or even because

he might have been expected to yield to it. However, a temptation may be so strong that we might expect any ordinary person to yield to it (even though a few people may in fact resist it), or, as one might say, it might be “more than human nature can stand.” In that sense it may be “irresistible.”

Some people, of course, find it much more difficult than others to resist temptation. Some, like kleptomaniacs, are “impelled” to act in the sense that deliberation neither plays, nor could play, any part in what they do. Such people might be distinguished from plain wrongdoers by the fact that nothing—not blame, punishment, praise, or rational argument—seems to affect their disposition to break the rules. Or, again, their actions may lack any point, or if they can be said to have any point, it is only in relation to a set of aims and standards of achievement so distorted and eccentric that they are intelligible only to a psychiatrist. The kleptomaniac who steals nylon stockings for which he has no possible use (according to ordinary standards of utility) might properly be said to be unable to help stealing them. Far more difficult is the case of the psychopath, who seems to have no wish to resist temptation or, rather, who knows that some of the things he wants to do are wrong in the sense that other people disapprove of them but on whom this knowledge enforces no internal restraint beyond prompting a degree of caution. Criminals of this type would once have been described as “wicked” but are now often described as incapable of self-control. To say, however, that they are not responsible for their acts creates the odd situation that anyone is liable to punishment who usually resists temptation but sometimes fails, whereas the man who never resists is not liable at all.

The determinist has a short way with these difficulties. Since everyone’s actions are the response of his character to a given set of circumstances, how can anyone ever be held responsible for his actions? We do what we must, given what we are, and what we are is the end of a causal chain going back to before we were born. If one knew a person well enough, one might predict that under given conditions he would commit a crime. Is this compatible with saying that he can choose whether to do so, or is his belief in his freedom to choose simply an illusion? Can the result of a genuine choice be predicted?

To say that something is predictable is not, however, the same as saying it is unavoidable. We can forecast a man’s actions just because we know the kind of choices that he regularly makes. The more we know of his dispositions and his preferences, the more likely we are to be right. But that does not mean that he never acts voluntar-

ily or that he never makes a real choice but only thinks he does. If all choices are illusions, what would a real choice be like? A man’s behavior may be predictable because he can be relied upon to do what is reasonable, but to act with good reason is the very reverse of being subject to an inner compulsion. An essential difference between voluntary and involuntary action is that it makes sense to speak of the motives, aims, and reasons for the former but only of the causes of the latter. It is only when a person’s behavior seems pointless or when explanations in terms of aims do not seem sufficient that we look for the kind of cause which would justify saying that he could not help himself. Of course, a complete account of voluntary and rational behavior must refer to causes as necessary conditions for action, but such causes would not constitute a sufficient explanation. An account of the electronic activity in the brain would not provide a sufficient explanation of a move in a game of chess unless the move was so completely and absurdly irrelevant that it had to be accounted for simply as the result of a nervous twitch. In that case, however, it would not really be a move in the game at all, not an action, indeed, but something that happens to the player. The weakness of the determinist position, insofar as it purports to undermine the notion of responsibility, is that it treats such abnormalities as the explanatory model for the normal.

It is arguable, in any case, that the concept of responsibility *requires* that human behavior be causally accountable rather than the reverse. As David Hume pointed out in *An Enquiry concerning Human Understanding*,

[Where actions] proceed not from some *cause* in the character and disposition of the person who performed them, they can neither redound to his honour, if good; nor infamy, if evil. ... The person is not answerable for them; and as they proceeded from nothing in him that is durable and constant, and leave nothing of that nature behind them, it is impossible [that] he can, upon their account, become the object of punishment or vengeance.

In Hume’s view universal causality is consistent with the concept of choice and is a necessary condition for responsibility and, therefore, for blame and punishment.

Strictly speaking, all that is necessary for a theory of punishment is that human conduct should be capable of being modified by threats. For some people—for instance, compulsive lawbreakers like kleptomaniacs—that is not the case. Others, however, commit crimes believing they can escape punishment; still others, in a spirit of rebellion, indifference, or, more rarely, of mar-

tyrdom, prefer to do what they want and risk the consequences rather than conform. Why they prefer it—what conditions account for their being the men they are—is irrelevant. To say “they prefer it” is to say they might have chosen to do otherwise but did not, and that is all that is necessary for the concept “responsibility.” To ask whether they were free to prefer otherwise, being what they were, is to ask whether they could choose to choose, and it is not clear that this really means anything. The experience of punishment may provide a reason for choosing differently next time, but to have a reason for choosing is not to be without a choice and, therefore, without responsibility.

EXTENUATION. Though a criminal may be held responsible for his actions, there may nevertheless be circumstances which, so it is said, diminish responsibility or extenuate guilt. Temptation or provocation, though not irresistible may have been very great. The offender may have had a good character, and there may be no reason to expect any future lapse.

In some cases mitigation of sentence on such grounds can be readily justified in utilitarian terms. Little is to be gained by punishing the obviously exceptional lapse; a very small penalty might be enough to dissuade other respectable people who might otherwise be tempted to imitate it and for whom the shame of being treated as a criminal, whatever the penalty, is usually deterrent enough.

However, it is not easy to show, at least in utilitarian terms, that mitigation is reasonable in all the instances in which it is commonly thought appropriate. Nor does everyone agree on what are extenuating circumstances. It is not self-evident that whoever is sorely (but not irresistibly) tempted should be treated more leniently than people who have done the same thing but under less temptation. A strong temptation might be withstood if there were sufficient counterinducement. Leniency might weaken the resolve of others in the future. Some people treat crimes of passion leniently; others would say that the temptation is so commonly felt that if people were not discouraged from taking the law into their own hands by treating offenses of this kind severely, such offenses would rapidly multiply. Again, some people would accept a plea of drunkenness as an extenuation of an offense, whereas others would consider it an aggravation.

It is doubtful whether our ideas on this aspect of punishment depend on utilitarian considerations. Nor is there any reason to suppose that any system of utilitarian argument could show them to be consistent and rational.

It was suggested earlier that though the criteria of morality and law, of blame and punishment, are not identical, they influence one another. If we blame people less for yielding to strong temptation, we also feel they deserve a less severe punishment. But this only shifts the question a step back. Why should temptation mitigate blame?

A possible answer might be that at least some temptations can be pleaded as partial justifications. Thus, a man who pleads that he killed someone to shorten his sufferings or a woman who kills her deformed baby is appealing to another moral principle to excuse the act. Similarly, a man who kills his wife’s lover might claim that his victim was violating his rights. These are not complete justifications, as a plea of self-defense would be, but they are excuses that count, as it were, against the initial presumption of guilt and so incline us to look at the offense more sympathetically and more leniently, whatever the advantages of severity in terms of deterrence, prevention, or reform. There is nothing irrational in striking a balance of desert.

But differences of opinion about a criminal’s deserts often turn not on the way such a balance is struck but on the extent to which his judges (or their critics) are able to comprehend his action. Anyone who could imagine himself tempted in similar circumstances would probably be more sympathetic than someone who could not and who would therefore see no reason for being indulgent. On the other hand, anyone who suspected that he himself might yield to such a temptation and who flinched from the possibility might react to it with very great severity indeed.

PUNISHMENT AND REFORM

There is no reason to suppose, then, that the sentencing practice of the courts will display rational and consistent principles; furthermore, any attempt to set up criteria of rational judgment on strictly utilitarian principles is likely to cut across deeply rooted moral convictions. Accordingly, some criminologists and psychiatrists, such as Eliot Slater and Bernard Glueck, and some penal reformers, such as Barbara Wootton, have swung away from the general conceptions of punishment and desert. Instead of asking what penalty is warranted by the crime, whether the agent was fully responsible for his action, whether circumstances exonerate him wholly or in part, they prefer to ask what kind of treatment is most likely to rehabilitate him, subject, of course, to the example it might set for others.

This comes very close to repudiating altogether the concept of punishment as a deliberate infliction of suffer-

ing, which the criminal deserves, consequent to a voluntary breach of the law. First, the treatment most likely to rehabilitate him need not be unpleasant (though if it is to instill a measure of discipline, it very well may be). And, second, avoiding the question of moral responsibility, the reformer also avoids the question of what the criminal deserves, because the reformer's prime concern is with the treatment he needs. Criminals would no more deserve punishment than the sick deserve medicine. Indeed, for such writers as Samuel Butler and the American lawyer Clarence Darrow, criminality is a kind of sickness to be treated rather than a wrong to be punished.

Attractive as this approach may seem on humanitarian grounds, it has at least one serious consequence. The concepts of responsibility and desert cannot be discarded without some loss. For it is not a necessary condition of medical treatment that a patient must have shown symptoms of a disease; those exposed to smallpox are vaccinated before they develop a fever. Without the principle that punishment must be deserved, there would be no obstacle to subjecting people likely to become criminals to corresponding forms of penal prophylaxis. Moreover, if we substitute for punishment the idea of rehabilitative treatment, there is nothing against sentencing a person of bad character to a severe course of treatment for the most trivial offense if his character would be better for it in the end. This would clearly be incompatible with the usually accepted principle that trivial offenses should not carry severe penalties.

Reformism of this kind is open to attack from another quarter. The point has been made by Hegel and Bernard Bosanquet, among others, that retributive punishment is a kind of tribute to the moral personality of the criminal. It is precisely as a morally responsible agent, recognized as capable of making reasoned choices and accepting the consequences, that the criminal is punishable. Bosanquet goes so far as to say that punishment is "his right, of which he must not be defrauded." It is to be distinguished, argued Bradley, from the discipline or correction appropriately administered to animals and children. Punishment "is inflicted because of wrongdoing, as desert, the latter is applied as means of improvement." Since rational adults are neither animals nor children, no one has the right to treat them as if they were. It might be similarly argued that lunatics are under tutelage because they are incapable of looking after their own interests and cannot be expected to respect those of other people. The sane criminal, on the contrary, can be made to pay for his antisocial choices in order to demonstrate to him and, through him, to others that crime does not pay, but it

diminishes his stature as a rational adult to deny that he is responsible for ordering his own life and to impose upon him ends of another person's choosing.

Nevertheless, retributivists have often been much concerned with moral reformation. They have insisted, however, that this was something the criminal must do for himself. Because it was associated with shame and rejection, punishment could bring the criminal up short and force him to reconsider his life in the light of society's condemnation of his actions. But the remorse that was a necessary condition for self-reformation was entirely dependent on the criminal's recognition that his punishment was deserved. Without that there could be no inward reformation, no reassertion of moral standards, but only a sense of resentment and injustice. Accordingly, punishment can yield the benefits of reform only if it is thought of, above everything else, as retributive—as the appropriate desert of a responsible guilty agent. It is this which distinguishes the retributive approach to moral reformation from the kind of utilitarianism which turns its back on desert and responsibility and is concerned only with the needs of rehabilitation.

It is, of course, an open question whether punishment ever does produce the kind of self-reformation the Hegelians had in mind or whether it does so more often than it produces a moral decay. Indeed, our knowledge of the facts of criminal behavior is probably far too scanty and uncertain for us to know how relevant much of the philosophical discussion of punishment really is. We cannot say for sure that a penal system is justified because it tends to reform criminals. Nor do we know, for that matter, whether the deterrent view of punishment is applicable to all kinds of crime. Many people commit offenses without seeming to take any account of consequences before they act, and they repeat the same offenses again and again in spite of punishment. Perhaps those who do not, would not repeat them even without punishment. Perhaps there would be no more cases of certain classes of crime than there are already; perhaps the only people to commit them are those who also do not take account of consequences before they act. It seems likely that some potential offenders are deterred from evading taxes or from smuggling by the threat of punishment, but is there any certain evidence that the threat of punishment deters anyone who would otherwise commit rape or arson?

Utilitarians tend to assume that punishment as an institution can be justified by its beneficial consequences, but the argument depends on certain a priori assumptions about criminal (or would-be criminal) behavior that may be greatly overintellectualized. However, even though

research should prove the usual utilitarian justifications for punishment groundless, that does not mean that some other, nonutilitarian justification is better. The proper procedure may well be to ask, with the utilitarian, whether the consequences are by and large beneficial; it is equally possible that punishment as an institution might fail that test. A theory of punishment that led to the conclusion that all punishment was wrong need be no more necessarily mistaken than a theory that led to a similar conclusion as regards, say, slavery, which, after all, was accepted as uncritically in Aristotle's day as punishment is today.

Bibliography

For a broad treatment of the subject, see A. C. Ewing, *The Morality of Punishment* (London: K. Paul, Trench, Trubner, 1929). For classic expositions of retributive positions, see Immanuel Kant, "Metaphysische Anfangsgründe der Rechtslehre," in *Die Metaphysik der Sitten* (1797), in *Werke*, Vol. VII (Berlin, 1922), translated by W. Hastie as *Kant's Philosophy of Law* (Edinburgh, 1887); G. W. F. Hegel, *Philosophie des Rechts* (1821), in *Werke*, Vol. VIII (Berlin, 1833), translated by T. M. Knox as *Hegel's Philosophy of Right* (Oxford: Clarendon, 1942). See also Ch. 8 of Bernard Bosanquet, *Philosophical Theory of the State* (London, 1899; 4th ed., Macmillan, 1923), and Essay 1 of F. H. Bradley, *Ethical Studies* (London, 1876; 2nd ed., rev., Oxford: Oxford University Press, 1927). Extensive bibliographic notes can be found in Giorgio Del Vecchio, *La giustizia*, which was originally published in *Annuario dell'Università di Roma* (1922–1923), 4th ed. (Rome, 1951), translated by Lady Guthrie as *Justice*, edited by A. H. Campbell (Edinburgh, 1952).

More recent analyses, mainly in retributive terms, can be found in J. D. Mabbott, "Punishment," in *Mind* 48 (1939): 152–167; C. W. K. Mundle, "Punishment and Desert," in *Philosophical Quarterly* 4 (16) (1954): 216–228; D. C. Hodges, "Punishment," in *Philosophy and Phenomenological Research* 18 (2) (1957–1958): 209 (a case for viewing punishment as reparation). K. Baier, "Is Punishment Retributive?," in *Analysis* 16 (2) (1955): 25–32, argues that the concept of punishment entails retribution but does not deal with problems of justification. See also A. R. Manser, "It Serves You Right," in *Philosophy* 37 (142) (1962): 293–306. H. J. McCloskey, "The Complexity of the Concepts of Punishment," *ibid.*, 307–326, draws attention to variety of contexts in which "punishment" is used and argues against analysis in terms of a standard case.

For classic statements of utilitarian positions, see C. B. Beccaria, *Dei delitti e delle pene* (1764); *An Essay on Crimes and Punishment, Translated from the Italian*, 4th ed. (London, 1785); Jeremy Bentham, *Introduction to the*

Principles of Morals and Legislation (1789), Wilfrid Harrison, ed. (Oxford, 1948), and *Traité de législation, civile et pénale*, E. Dumont, ed. (Paris, 1802), translated by R. Hildreth as *Theory of Legislation*, C. K. Ogden, ed. (London, 1931). See T. H. Green, *Lectures on the Principles of Political Obligation*, in *Works*, edited by R. L. Nettleship, Vol. II (London, 1885), or in a separate edition, with an introduction by A. D. Lindsay (London: Longman, 1941); Green repudiates retributivism but stresses moral reformation as a function of punishment and, therefore, the importance of the concept of desert (cf. Bosanquet, *op. cit.*). See also Vol. I of Hastings Rashdall, *Theory of Good and Evil*, 2 vols. (Oxford: Clarendon Press, 1907; 2nd ed., 1924).

The following examples of recent analyses of the problems of punishment are mainly utilitarian in emphasis but try to allow some place for retributivism in a general theory. In W. D. Ross, *The Right and the Good* (Oxford: Clarendon Press, 1930), especially Appendix II, Ross argues that the state is entitled to punish offenders in the public interest because by invading the rights of others, they forfeit their own claim to protection. On this subject see also A. G. N. Flew, "The Justification of Punishment," in *Philosophy* 29 (3) (1954): 291–307; H. L. A. Hart, "Prolegomenon to the Principles of Punishment," in *PAS* 60 (1959–1960): 1, and "Murder and the Principles of Punishment: England and the United States," in *Northwestern University Law Review* 52 (4) (1957): 433. Also, see A. Quinton, "On Punishment," and Stanley I. Benn, "An Approach to the Problems of Punishment," in *Freedom and Responsibility*, edited by Herbert Morris (Stanford, CA: Stanford University Press, 1961); J. Rawls, "Two Concepts of Rules," in *Society, Law, and Morality*, edited by F. A. Olafson (Englewood Cliffs, NJ: Prentice-Hall, 1961); Stanley I. Benn and R. S. Peters, *Social Principles and the Democratic State* (London: Allen and Unwin, 1959), especially Chs. 8–9. Patrick J. Fitzgerald, *Criminal Law and Punishment* (Oxford: Clarendon Press, 1962), deals with the philosophical problems in the broad context of English criminal law. For a discussion of the relations of law, morality, and punishment, see Patrick Devlin, *The Enforcement of Morals* (London: Oxford University Press, 1965), and H. L. A. Hart, *Law, Liberty and Morality* (Stanford, CA: Stanford University Press, 1963).

For discussions of free will, determinism, and responsibility in relation to punishment, see H. L. A. Hart, Paul Edwards, and John Hospers, symposium on "Determinism and Freedom in Law and Ethics," in *Determinism and Freedom*, edited by Sidney Hook (New York: New York University Press, 1958); J. D. Mabbott, "Freewill and Punishment," in *Contemporary British Philosophy*, edited by H. D. Lewis, 3rd series (London, 1956). In Barbara Wootton, *Social Science and Social Pathology* (London: Allen and Unwin, 1959), there is a survey of recent trends in psychiatric and criminological studies critical of the concept "responsibility"; see especially Ch. 8. For a criticism of these trends, see H. L. A. Hart, *Punishment and the Elimination of Responsibility* (Oxford: Clarendon Press, 1968). *Freedom and Responsibility* (see above) is a useful collection of readings on various aspects of the problem of responsibility, including its relation to punishment, extenuation, and so on; it includes an extensive bibliography.

Stanley I. Benn (1967)

PUNISHMENT [ADDENDUM]

Since 1967, preventive theories of punishment (whether strictly utilitarian or more loosely consequentialist) have entered a long decline, beginning with the virtual disappearance of reform theory in the 1970s. Crowding them out are various alternatives generally categorized as “retributive.”

All preventive theories treat punishment as (primarily) a means of controlling objectionable behavior. Insofar as they propose to justify punishment on the assumption that penalties can be tuned to achieve a certain degree of social control, they are empirically vulnerable (as well as morally vulnerable for ignoring justice). What had become clear by the 1970s was that social science could not then, or in the foreseeable future, give preventive theories much empirical content. Social science could not, that is, say what effect, if any, statutory penalties, rehabilitation, exemplary punishments, or even the incapacitation of criminals would have on the crime rate. If even relatively crude tuning of penalties to consequences is in practice impossible, preventive theories cannot justify choosing one system of punishment over another, much less one punishment over another.

In contrast to preventive theories, retributive theories do not seek to justify punishment by pointing to an empirical relation between punishment and “consequences” (such as a certain crime rate). For retributive theories, the relation between punishment and its justification is conceptual (“internal,” as Georg Wilhelm Friedrich Hegel would say). No retributivist need deny that punishment has some general tendency to control crime or that that tendency is a reason to have some punishment system rather than none. All retributivists need deny is that punishment’s (actual or probable) tendency to control crime matters much for understanding why we should (or should not) have this institution, practice, or act of punishment rather than another.

Retributive theories may be divided into two importantly different kinds: moralistic and legalistic. Moralistic retributivism has three (main) divisions: desert, paternalist, and condemnatory theories. *Desert* theory takes it as (more or less) brute fact that wrongdoing deserves an unpleasant response, that is to say, punishment. Punishment is justified because it is deserved. Nothing more need be said. *Paternalist* theory holds that all justified punishment, or at least all justified punishment of rational agents, must aim at a certain good for those punished. This good may be subjective (R. A. Duff’s

“penance”) or objective (Robert Nozick’s “connection with correct values”). *Condemnatory* theory, in contrast, understands punishment as (primarily) an “expressive act” not meant to benefit anyone.

All three varieties of moralistic theory are retributive (in the sense used here) because all seek to achieve a good that is conceptually related to punishment. For desert theories, that good is simply giving wrongdoers what they deserve. Degree of desert determines severity of punishment. For paternalist theories, the justification of punishment lies in the way punishment treats the wrongdoer—for example, as a being capable of learning justice from the punishment appropriate to the crime. The seriousness of the wrong determines what penalty is appropriate to teach the lesson that the crime shows the wrongdoer needs to learn. For condemnatory theories, the justification of punishment lies in what the punishment “expresses.” The denunciation should be as emphatic as the crime was bad; the more severe the punishment, the more emphatic the denunciation is.

While desert theories seem to be the direct descendants of traditional retributivism, paternalist theories superficially resemble traditional *reform* theories, and condemnatory theories similarly resemble traditional *deterrence* theories (denunciation resembling a deterrent threat). Both nonetheless differ fundamentally from the corresponding preventive theory. According to the paternalist theory (in its pure form, at least), punishment would be justified even if wrongdoers never repent or learn as a result of punishment. What is important—important because it respects the moral personality of the wrongdoer—is that the right punishment be imposed with the right intention. In much the same way, according to the condemnatory theory (in its pure form), punishment is justified even if emphatic denunciation has no effect on the crime rate or on the individual’s later conduct. Reaffirming the wrongness of an act is good in itself, good enough (all else being equal) to justify the punishment.

All moralistic theories share the assumption that punishment belongs to ordinary morality (rather than to the law in particular). Moralistic theories use ordinary moral practices (such as disciplining children) to understand punishment (with legal punishment only a special case). Moralistic theories differ primarily in the part of ordinary morality to which they assign punishment. Desert theory treats punishment as (negative) rewarding; paternalist theory treats punishment as correction or teaching; and condemnatory theory treats punishment as moral statement. Other moralistic theories are possible,

for example, one treating punishment as a form of self-defense or satisfaction of a promise.

Legalistic theories, in contrast, assume that (justified) punishment is a practice (largely) confined to (relatively just) legal systems. The only important form of legalistic retributivism today is “the fairness theory” (also known as “benefits-and-burdens,” “reciprocity,” or “unfair advantage” theory). It holds that legal punishment (and close analogues) is justified insofar as it supports the (relatively) just distribution of benefits and burdens that a (relatively just) legal system (or similar practice) creates. A relatively just legal system is to be thought of as a cooperative enterprise from which each benefits if others generally do their part and in which doing one’s part will sometimes be burdensome. According to the fairness theory (in its pure form at least), the institution of legal punishment is justified if punishment keeps lawbreakers from gaining an unfair advantage over the law-abiding. Punishment, if just, necessarily takes back the unfair advantage the crime as such takes (or, at least, some fair equivalent of that advantage). Though the fairness theory has an obvious affinity to certain theories of distributive justice (especially, Rawlsian social contract), it presupposes no particular theory. All it presupposes is that there can be an equivalence between crime and (just) punishment assuring that (in general at least) legal punishment of certain people in certain ways will (as a conceptual matter) increase (or at least help to maintain) overall distributive justice (however defined). Explaining that presupposition has proved difficult.

See also Hegel, Georg Wilhelm Friedrich; Nozick, Robert; Presupposition; Rawls, John.

Bibliography

For some sense of the history of punishment since 1967, compare Marvin Zalman, “The Rise and Fall of the Indeterminate Sentence,” *Wayne Law Review* 24 (1977): 45–94; Nigel Walker, *Punishment, Danger, and Stigma* (Oxford: Blackwell, 1980); and Annika Snare, ed. *Beware of Punishment*, *Scandinavian Studies in Criminology*, 14 (1995).

For some broad general treatments of punishment theory, see Ted Honderich *Punishment: The Supposed Justifications* (London: Hutchinson, 1969); Hyman Gross, *A Theory of Criminal Justice* (New York: Oxford University Press, 1979); C. L. Ten, *Crime, Guilt, and Punishment: A Philosophical Introduction* (Oxford: Clarendon, 1987); Igor Primoratz, *Justifying Legal Punishment* (Atlantic Highlands, NJ: Humanities Press International, 1989); and Michael Moore, *Placing Blame: A General Theory of the Criminal Law* (Oxford: Clarendon, 1997). Comparison of these works (spaced about a decade apart) suggests the increasing

importance of retributivism, even when (as with Ten) the author himself argues for a preventive theory.

For some important criticism of retributivism, see Richard W. Burgh, “Do the Guilty Deserve Punishment?” *Journal of Philosophy* 79 (1982): 193–210; John Cottingham, “Varieties of Retribution,” *Philosophical Quarterly* 29 (1979): 236–246; John Braithwaite and Philip Pettit, *Not Just Deserts: A Republican Theory of Criminal Justice* (Oxford: Clarendon, 1990), ch. 8–9; David Dolinko, “Some Thoughts about Retributivism,” *Ethics* 101 (1991): 537–559; David Dolinko, “Retributivism, Consequentialism, and the Intrinsic Goodness of Punishment,” *Law and Philosophy* 16 (1997): 507–528; and Nigel Walker, “Even More Varieties of Retribution,” *Philosophy* 74 (1999): 595–605.

For the best recent statement of the desert version of retributivism, see D. E. Scheid, “Constructing a Theory of Punishment, Desert, and Distribution of Penalties,” *Canadian Journal of Law and Jurisprudence* 10 (1997): 441–506. Other important discussions include Lawrence H. Davis, “They Deserve to Suffer,” *Analysis* 32 (1972): 136–140; John Kleinig, *Punishment and Desert* (The Hague: Nijhoff, 1973); W. A. Parent, “The Whole Life View of Criminal Desert,” *Ethics* 86 (1975): 350–354; and Douglas N. Husak, “Why Punish the Deserving?” *Nous* 26 (1992): 447–464.

For the most influential statements of the paternalistic theory, see Herbert Morris, “A Paternalistic Theory of Punishment,” *American Philosophical Quarterly* 18 (October 1981): 263–271; Robert Nozick, *Philosophical Explanations* (Cambridge, MA: Harvard University Press, 1981), pp. 363–397; Jean Hampton, “The Moral Education Theory of Punishment,” *Philosophy and Public Affairs* 13 (1984): 208–238; and R. A. Duff, *Trials and Punishments* (Cambridge, U.K.: Cambridge University Press, 1986).

Among important discussions of the expressive theory are: A. J. Skillen, “How to Say Things with Walls,” *Philosophy* 55 (1980): 509–523; Igor Primoratz, “Punishment as Language,” *Philosophy* 64 (1989): 187–205; Michael Davis, “Punishment as Language: Misleading Analogy for Desert Theorists,” *Law and Philosophy* 10 (1991): 310–322; Andrew von Hirsch, *Censure and Sanctions* (Oxford: Clarendon, 1993). Though Joel Feinberg’s influential “The Expressive Function of Punishment,” *Monist* 49 (1965): 397–423, is usually treated as a seminal statement of the expressive theory—as reprinted in Feinberg’s *Doing and Deserving: Essays in the Theory of Responsibility* (Princeton, NJ: Princeton University Press, 1970)—it is not. It actually proposes to revise the standard (Hart-Flew) definition of punishment, something necessary because of Feinberg’s legal positivism. Since retributivism aims at justice, not mere social control, retributive expressivists do not need to fiddle with the definition of punishment to distinguish between (justified and so, expressive) punishment and mere penalties. Retributivists have therefore generally ignored Feinberg’s proposal (while citing him as pointing to the expressive function of punishment).

For some examples of moralistic retributivism relying neither on desert, paternalism, nor condemnation, see: Phillip Montague, *Punishment as Societal Defense* (Lanham, MD: Rowman & Littlefield, 1995); and Jerry Cederblom, “The Retributive Liability Theory of Punishment,” *Public Affairs Quarterly* (1995): 305–315.

For important discussions of the fairness theory (and related issues), see: Herbert Morris, "Persons and Punishment," *The Monist* 52 (1968): 475–501; John Finnis, "The Restoration of Retribution," *Analysis* 32 (1971–1972): 131–135; J. Murphy, "Marxism and Retribution," *Philosophy and Public Affairs* 2 (1973): 217–243; Wojciech Sadurski, *Giving Desert its Due: Social Justice and Legal Theory* (Dordrecht: Kluwer, 1985); George Sher, *Desert* (Princeton, NJ: Princeton University Press, 1987); Richard Dagger, "Playing Fair with Punishment," *Ethics* 103 (1993): 473–488; and Anthony Ellis, "Punishment and the Principle of Fair Play," *Utilitas* (1997): 81–97. For an example of a legalist retributivism that at least seems not to be an instance of the fairness theory, see Margaret R. Holmgren, "Punishment as Restitution: The Rights of the Community," *Criminal Justice Ethics* (1983): 36–49.

For recent examples of the application of retributivism to various practical problems in the theory of punishment, see Kathleen Dean Moore, *Pardons: Justice, Mercy, and the Public Interest* (New York: Oxford University Press, 1989); Jeffrie G. Murphy and Jean Hampton, *Forgiveness and Mercy* (Cambridge, U.K.: Cambridge University Press, 1990); Michael Davis, *To Make the Punishment Fit the Crime: Essays in the Theory of Criminal Justice* (Boulder, CO: Westview, 1992); R. A. Duff, *Criminal Attempts* (Cambridge, U.K.: Cambridge University Press, 1996); Andrew von Hirsch and Andrew Ashworth, eds. *Principled Sentencing: Readings on Theory and Policy* (Oxford: Hart, 1998); and Stephen Kershnar, "An Argument for the Use of Torture as Punishment," *Hamline Journal of Public Law and Policy* (1998): 497–528.

Recent positive work on deterrence seems to be more than a decade old. See, for example (beside Ten, 1987, above), D. Schmitz, "Deterrence and Criminal Attempts," *Canadian Journal of Philosophy* 17 (1987): 615–623; Daniel M. Farrell, "On Threats and Deterrence," *Social Theory and Practice* 15 (1989): 367–394; and B. Sharon Bird, "Kant's Theory of Punishment: Deterrence in its Threat, Retribution in its Execution," *Law and Philosophy* 8 (1989): 151–200. Reform theory may be reviving as "restorative justice" within the victim's rights movement (but with a strong retributive overlay). See, for example, Charles K. B. Barton, *Getting Even: Revenge as a Form of Justice* (Chicago: Open Court, 1999).

Michael Davis (2005)

PUTNAM, HILARY

(1926–)

Hilary Putnam, after receiving a BA from Pennsylvania (1948) and a year spent at Harvard (1948–1949), studied at the University of California, Los Angeles, taking his doctorate in 1951 with a dissertation titled "The Concept of Probability: An Application to Finite Sequences." He taught at Northwestern (1952–1953), Princeton (1953–1961) and MIT (1961–1965), becoming Walter Beverly Pearson professor at Harvard in 1965. From 1995 to 2000,

he served as Cogan University Professor there, becoming emeritus in 2000. He has been influential in most areas of philosophy, particularly in the philosophy of language, of logic, of mathematics, and of science.

Putnam is sometimes thought of as often changing his mind. (See, for example, the *Dictionary of Philosophers' Names*.) Sometimes he has. But in central respects he has held a single, though developing, position since the mid-1950s, a position that in some aspects resembles the later Ludwig Wittgenstein's. This entry sets out some constant central themes.

Putnam was among those American philosophers to benefit directly from the intellectual exodus from Europe caused by Nazism. He was a student of Rudolf Carnap and of Hans Reichenbach. Though his approach to issues is quite different from theirs, Reichenbach in particular had a lasting and often acknowledged influence on Putnam's thought. Putnam's innovations stand out when it is noted. In *Realism with a Human Face* (1990, p. 289), Putnam remarks,

In *Theory of Relativity and A Priori Knowledge* (1922) Reichenbach listed a number of statements ... each of which Kant would have regarded as synthetic *a priori*, and each of which can be held immune from revision ..., but which *collectively imply statements that are empirically testable*, and that Kant would, therefore, have to regard as *a posteriori*.

Certain principles had, in Immanuel Kant's time, as good a claim as any to fix how particular spatial, temporal, and other concepts are to be applied, and thereby which concepts those were; to be intrinsic to the concepts involved, thus "conceptual truths," thus *a priori*. Relativity theory allows us to see how they are at least jointly testable, so that some may turn out false. Such, it seems, is a fate to which *a priori* truths are liable.

Putnam reports Reichenbach as making a related point to his classes. Considering questions such as "How can we show that that blackboard is wider than this ash-tray?" he argued that any system of measurement, or of observation, treats some propositions that seem empirical (such as "mere translation does not make things grow or shrink") as axiomatic. One cannot sensibly apply the system while doubting these propositions; they are not subject to confirmation or refutation within the system. But it could prove reasonable to replace the system with another in which these propositions are testable, so possibly false. In that sense they are empirical.

There are two contrasting reactions to these points. One is: What this shows is that every concept commits itself to a particular empirical theory. If the theory proves false, then the concept is incoherent, so without application and to be discarded. This was Paul Feyerabend's reaction, and it is also Paul Churchland's.

The other reaction is: If we are confronted with situations that force giving up what seemed conceptual truths, it may appear that the concepts whose applications seemed to be governed by those principles are, in fact, otherwise governed. Perhaps the application of the concept "straight line" to items in the world is not governed by the Euclidean parallel postulate, but rather in such and such other way. That reaction grants face value to Reichenbach's point that the same proposition that is axiomatic in one system may be testable and false in another. This was Putnam's reaction. He developed the position and drew its implications in a powerful series of papers in the 1950s and 1960s (see Putnam, 1962a–d). Part of the idea is that what principles govern the application of a concept depends in part on how the world in fact is. Putnam defined that role for the world in "The Meaning of 'Meaning'" (1975). This last article, though not published until 1975, was completed by 1968.

By the early 1970s, Putnam had begun to emphasize some new themes. For one thing, he became increasingly impressed with what he calls the "interest relativity" of such notions as explanation and cause. The general point is: What a concept counts as applying to—the correct way of applying it—varies with the circumstances in which it is to be applied. A concept may count, on one occasion, as fitting what it does not count as fitting on another. That is continuous with Putnam's earlier reaction to Reichenbach. The point then was: What it is reasonable to judge as to how a concept operates depends on the conditions in which such judgments are made. The point now is: What those conditions are depends not just on how the world is, but may vary from occasion to occasion, given the world as it is. Not coincidentally, this point went along with other developments in Putnam's thought.

The first of these developments is what he calls "internal realism," first presented in 1976, and amplified in his writings of 1981, 1983, 1987a, 1987b, and elsewhere. The position includes four points. First, there are mundane, true things to say about what our words and thoughts are about: "the word 'gold' means (refers to) gold; this is gold"; "This is a chair; this is what 'chair' refers to," and so forth. Second, there are philosophical dicta that sound much like such mundanities, or their denials, or generalizations of these, but that say, or try to

say, something quite different. They are bad answers to the following pseudo-problem. On the one hand, there are thoughts and words—items that purport to represent the world as being thus and so; on the other hand, the items the world in fact contains, which are what and how they are independent of what we think, or do not think, about them. How are our words and thoughts related to these items? How, if at all, does their truth depend on how those items are? And how could they be so related? Internal realism holds that the problem rests on a mistake; hence so do any 'solutions', which take it at face value.

Third, the mundane remarks (point one) are correct because they are a feature of how these words are (or are to be) used. But that formulation depersonalizes things misleadingly. The standard for the correctness of a statement cannot be fixed independently of what users of the relevant words and concepts—that is, human beings—are prepared to recognize as correct: What Putnam identifies as our (human) perceptions of rationality and reasonableness. What it is for a statement to be correct depends on the sorts of beings we are, and is not reducible to some set of principles that would have to hold anyway. Fourth, it is part of what we are prepared to recognize as rational that any concept might be applied correctly in different ways in different circumstances. What sometimes counts as the cause of the explosion may not at other times. It is because human rationality is occasion-sensitive that the problem mentioned in point two is a pseudo-problem. We cannot sensibly take a "God's-eye view" of how we relate to the world, trying to say how our concepts would apply without us.

The occasion-sensitivity of rationality does not mean that truth is relative, or that there are no objective facts—given a framework, or setting, in which concepts are to be applied. Nor does giving up on a God's-eye view mean a deflationist account of truth. Putnam insists that we cannot comprehend what truth is without understanding the role of truth in our lives, notably in our activities of asserting, and of treating assertions in the ways we do; and that deflationism does not help us understand the role of truth in human life.

In arguing against the possibility of a God's-eye view, Putnam has produced what are probably his most discussed arguments. In one he identifies the God's-eye view (what John McDowell has called "the view of the cosmic alien") as one from which we may consider our own language as an uninterpreted calculus with a range of possible interpretations, and then ask which interpretation is the right one. In what he first saw as a generalization of the Skolem paradox, he argues that, in that case, *nothing*

could make one interpretation the right one, so we could not ever be talking about anything (or about one thing rather than others). But we cannot pose serious problems without talking about definite things. This is a reductio of the idea of a God's-eye view (see "Models and Reality," *Philosophical Papers*, Vol. 3).

In another argument Putnam considers the (apparent) question whether we might be brains in a vat: that we are, and always have been, nothing but brains, kept alive by a bath of nutrients, fed computer-generated stimuli through electrodes. He argues that if the God's-eye view is possible, then that we are, and that we are not such brains should both be possibilities. But for the words of the question to mean what a God's-eye view requires them to mean we must be using them in ways that entail that we are not brains in vats. For, as argued in "The Meaning of 'Meaning,'" what our words mean depends, *inter alia*, on how we are in fact connected to the world, and not just on what we may anyway be aware of. For our "brain" to mean *brain*, and our "vat" to mean *vat*, we must be connected to the world as brains in ways vats could not be. So we cannot formulate what, from a God's-eye view, ought to be a possibility, in a way that makes it possible. That is another reductio of the idea of a God's-eye view (see Putnam 1981).

Equally important to internal realism are Putnam's arguments against a causal theory of reference: Arguments, based on the interest-relativity of causation, that our being causally linked to the world as we, in fact, are is not enough in itself to make some one interpretation of our language correct—once it is granted that the language we speak may coherently be viewed by us as less than fully interpreted, so open to interpretation. These arguments appear in many replies to critics, and notably in "Realism with a Human Face" (1990).

At about the time Putnam began to develop internal realism, he also began to change his way of thinking about human psychology, rejecting a picture of it, and with that, a view he once espoused—functionalism. Viewed one way, a human being is an organism constructed in a particular way, a particular battery of mechanisms arranged to interact with each other and the environment in given ways. If, while taking that view, we ask what it is for someone to believe that Mars is a planet, or to have any propositional or other attitude—to be in a mood, experience an emotion, and so on—it is tempting to look for an answer by trying to identify some state(s) of some mechanism(s) such that for someone to believe that is for him to be structured like that. In that frame of mind, for example, one might speak seriously of someone

having a "token of a mentalese sentence" in his "belief box." This is the picture Putnam rejects.

Against it Putnam notes that to ascribe belief to someone is to relate that person to the world as we view it, and to ourselves, as on the same side as ours, or a different one, with respect to such and such question as to how the world is, and so on. Given internal realism, this means that there will be different truths to tell on different occasions as to what a given person, as he is at a given time, then believes. So for someone to be as said to be when we say him to believe thus and so, cannot be for him to have some particular mechanism, otherwise identifiable, in some particular state. And so on for other mental states (see Putnam 1989).

Putnam has been refining the ideas discussed above, notably the idea of a distinction between ordinary and philosophic statements, and applying them in new areas, such as philosophy of mathematics. The above indicates a few main themes, omitting Putnam's striking arguments for them.

PYRRHO

(c. 360–c. 270 BCE)

Pyrrho of Elis is much less well known than the eponymous philosophy he inspired, Pyrrhonism. Diogenes Laertius, in his biography of Pyrrho in *Lives of Eminent Philosophers*, offers his usual mixture of anecdote, scandal, and unreliable doctrinal information (9.61–70). Thus Pyrrho was said to have had no concern for his own safety and to have been rescued from precipices and oncoming traffic by the timely interventions of his (presumably nonskeptical) friends (9.62). Aenesidemus rejected such fables, "saying that while he did philosophize in accordance with suspension of judgment, he did not act in a heedless manner" (9.62). Such stories, as well as ones presumably designed to exalt his image, such as one that claims that he demonstrated his unworldly indifference by washing pigs (9.66), are apocryphal, but they indicate what others apparently took his skeptical detachment to amount to.

He is also said to have traveled with Anaxarchus as far as India, where he consorted with the "gymnosophists," the naked philosophers, which led him "to philosophize in the noblest manner, adopting non-apprehension (*akatalēpsia*) and suspension of judgment (*epochē*); he said that nothing was good or bad, just or unjust, and that in all cases nothing is really true, but that men act by law and custom in all cases; for each thing is no more (*ou mallon*) thus than not" (9.61). This suggests that Pyrrho did indeed institute much of what was to become distinctive about later Pyrrhonism, but it also implies that he was primarily concerned with ethical questions (broadly construed)—an impression confirmed by some later evidence, most noticeably that of Cicero, who treats him exclusively as originating an obsolescent quietist ethics.

However, other testimonies suggest a broader engagement with more general epistemological themes. Pyrrho himself wrote nothing, but a disciple, Timon of Phlius, lauded his master in both prose and poetry, of which some seventy-one fragments survive. Some are devoted to exalting Pyrrho's imperturbable and noble character at the expense of the "vanity" of other philosophers. But more important for an assessment of Pyrrho's philosophical position is a report of a passage from one of Timon's prose works, embedded in an antiskeptical tract of the Aristotelian Aristocles of Messene, and itself preserved by way of the Christian Eusebius. (Such is the tortuous route of the early skeptical tradition, and attempting to purge such intrinsically hostile reports of later accretions of distortion and selectivity is a serious scholarly challenge.)

Aristocles reports Pyrrho as holding that "we are so constituted as to know nothing," and hence that all inquiry is pointless. Since for Sextus Empiricus and other later skeptics, the first claim would be unacceptably (if negatively) dogmatic, and since Sextus defines the Pyrrhonian way as one of continued (if unrequited) inquiry, this may be a misrepresentation on Aristocles' part. But it is equally possible that Pyrrho did conclude that nothing was knowable and inquiry futile, and that the subsequent rejection of these views was a later development. This latter possibility gains support from recent suggestions (see Bett 2000) that Pyrrho was not in fact the skeptical hero that later skeptics, such as Sextus, wanted to paint him as for ideological reasons of their own. Both Aenesidemus and Sextus treated Pyrrho as an archetypical role model. But Sextus, while remarking that "the skeptic school ... is called 'Pyrrhonian' from the fact that Pyrrho seems to have taken up scepticism more thoroughly and conspicuously than any of his predecessors" (1.7), rarely mentions him by name elsewhere in his large *oeuvre*. And Diogenes reports that one Numenius claimed that Pyrrho dogmatized, that is, held positive tenets (9.68). If this is right, then Pyrrho might have become a model because of his legendary imperturbability, rather than because of any practice of skeptical argumentation. Working against this view are some of the citations quoted and Diogenes' claim that Pyrrho was skilled in dialectical argument (9.64), which was to be the hallmark of later skepticisms.

At all events, Timon, as reported by Aristocles, states that according to Pyrrho, "[i] One must consider three questions: First, how are things by nature? Second, what should our attitudes toward them be? Third, what will be the result of adopting such an attitude? ... [ii] Pyrrho

declared all things equally indifferent, unmeasurable, and undecidable; [iii] for this reason [or since] neither our sensations nor our judgments are true or false. [iv] Consequently, we should not put our trust in them but should be without opinion, uncommitted, and unswayed, saying of each thing no more [*ou mallon*] [a] that it is than [b] that it is not, or [c] that it both is and is not, or [d] that it neither is nor is not. [v] For those thus disposed, the consequence will be first nonassertion [*aphasia*] then tranquility [*ataraxia*]” (Aristocles, in Eusebius, 14.18.2; = Long and Sedley Fr. 1F–5; my translation).

This is by far our most important philosophical testimony for Pyrrho, and it is based upon (and perhaps reports verbatim) a text of Pyrrho’s own pupil. It is, however, multiply difficult to interpret. The following interpretation is one way to try to make sense out of this difficult passage. The “things” (*pragmata*) of [i] may be states of affairs in the world or, more vaguely, subjects of possible cognition. “Indifferent” (*adiaphora*) in [ii] may perhaps be better rendered “undifferentiable” (thus making the claim not about the metaphysical condition of things but rather about our epistemic position with regard to *pragmata*). “Since,” the alternative connective of [iii], represents a textual conjecture that has won some scholarly support, and it has the obvious effect of reversing the direction of dependence between [ii] and [iii]. The scope of “no more” in [iv] is unclear (the sentence is syntactically ambiguous); it may govern four disjuncts (including disjuncts [c] and [d]), rather than just the first two. Finally, the precise sense of “aphasia” in [v] is disputed.

With the connective “for this reason” in [iii] (the reading of the manuscripts), the assertion is that the indeterminacy of things renders our sensations and judgments about them neither true nor false. At first sight, this seems to be a strange inference. (Does not indeterminacy simply render them false, insofar as they make positive claims that fail to correspond to the indeterminate facts?) Yet the assertion can be made intelligible if we suppose that for a claim of the form “ x is F ” to be true, x must be unequivocally F , and equally for it to be false, x must be wholly not F . Thus, because of the indeterminacy in things, any unequivocal statement of the form “ x is F ” will be partly true and partly false, and hence neither wholly true nor wholly false. Consequently, withholding strong belief and commitment makes sense. (In favor of the manuscript reading, the sequence of consequence is maintained: from states of affairs, via epistemic consequences, to epistemic attitude, to pragmatic consequence.) In addition, the account of truth just given

supports the interpretation that “no more” in [iv] has narrow scope, that is, that [c] and [d] are alternative ways of describing the counterpoise between [a] and [b]. To get this interpretation, we have to understand “it is” to mean “it is unequivocally” in [a] and [b], but not in [c] and [d].

The upshot, then, is that we will make no statements; not that we will literally say nothing, but that we will express no strong commitment to the unequivocal truth of our first-order remarks about the world. And when we attain this state, tranquility will follow like a shadow. As later skeptics put it, once one stops seeking to make (and support) unequivocal claims about the world, all one’s initial anxiety (apparently caused by the second-order belief that there *should* be answers to such questions and the consequent frustration of not finding them) vanishes. If all this is right, then Pyrrho really was a recognizable precursor to the later skepticism that took his name. Yet Pyrrho was not a thoroughgoing skeptic, for as the interpretation offered above suggests (but does not demand), Pyrrho did commit himself to speculations at least about the actual (Heraclitean) state of affairs of things in a way that Sextus Empiricus at least (although perhaps not Aenesidemus) would have found anathema.

PYRRHONIAN PROBLEMATIC, THE

KNOWLEDGE AND JUSTIFICATION

If a belief is to count as knowledge, then it must be true. But truth is not enough: lucky guesses and, more generally, beliefs that are only accidentally related to the facts

they purport to describe do not amount to knowledge. What else, besides truth, is needed for a belief to count as knowledge, then? There is no agreement regarding how to fully answer that question, but there is a line of thought regarding how to begin such an answer that is widely shared: for a belief to amount to knowledge it has to be justified or supported by reasons, or rationally grounded, or warranted, or have some sort of positive epistemic status. (These, and other, words are sometimes used as synonyms, whereas sometimes they are intended to mark important epistemological distinctions. I use them interchangeably.) The justification in question here is usually qualified as epistemic, to distinguish it from the kind of justification that, for example, an assassin's mother might have in believing that her son is innocent despite mounting evidence against him.

It is possible to adopt many different attitudes with respect to any proposition p (say, the proposition that Paris is the capital of France). For instance, it is possible to believe that Paris is the capital of France, to be happy that Paris is the capital of France, to hope that Paris is the capital of France, and so on. Some of these attitudes can be called doxastic attitudes. What distinguishes a doxastic attitude from other attitudes we can adopt toward a proposition is that one can be justified or unjustified (in the epistemic sense) in adopting a doxastic attitude.

There are three basic doxastic attitudes: belief, disbelief, and suspension of judgment. (It might be that there are other attitudes that we might be justified or unjustified, in the epistemic sense, in adopting, but belief, disbelief, and suspension of judgment are basic in the sense that any other doxastic attitude will be such only because it entails one of these three basic attitudes.) To disbelieve that Paris is the capital of France is to believe that it is not true that Paris is the capital of France (and so, depending on how you count, you might think that there are only two basic doxastic attitudes: belief and suspension of judgment). To suspend judgment with respect to the proposition that Paris is the capital of France is to be in a mental state that is opposed both to believing and disbelieving the proposition. Suspension of judgment must therefore be carefully distinguished from having no attitude whatsoever with respect to a certain proposition. There is a difference between never having considered the question whether there is an even number of stars in the Milky Way and, having considered it, suspending judgment with respect to the question.

ACADEMIC AND PYRRHONIAN SKEPTICISM

If the connection between knowledge and justification presented earlier is correct, then we can know a proposition only if we are justified in believing it. Skepticism with respect to a range of propositions is the claim that the only justified attitude with respect to the propositions in that range is to suspend judgment. We are all skeptics, in this sense, with respect to some range of propositions. For instance, it seems obvious that the only correct attitude with respect to the proposition that there is an even number of stars in the Milky Way, once we have considered it, is to suspend judgment. This is ordinary skepticism. But most of us are nonskeptics with respect to many propositions. For instance, it seems obvious that the only justified attitude with respect to the proposition that Paris is the capital of France is to believe it, whereas the only justified attitude with respect to the proposition that Tony Blair is the president of the United States is to disbelieve it. Philosophical skepticism extends well beyond ordinary skepticism, claiming that we should suspend judgment with respect to propositions that we ordinarily think we are justified in believing.

It is customary to distinguish between two different kinds of philosophical skepticism, which can be called, following an ancient tradition, Academic skepticism and Pyrrhonian skepticism. Academic skepticism referred originally to a phase in the history of Plato's Academy that stretched approximately from the third to the early first century BCE. The main figures of Academic skepticism were Arcesilaus (mid-third century BCE), Carneades (mid-second century BCE), and Clitomachus (d. 110/109 BCE). The main sources for Pyrrhonian skepticism are the writings of Sextus Empiricus in the late second century CE.

Academic and Pyrrhonian skepticism differ in the scope of propositions that, according to them, we should suspend judgment about. Let's call those propositions that do not contain any epistemic concepts ordinary propositions and let's call those propositions to the effect that someone knows an ordinary proposition can be called epistemic propositions.

Academic skeptics think that the only justified attitude with respect to most (perhaps all) ordinary propositions is suspension of judgment. However, Academic skeptics do not suspend judgment with respect to epistemic propositions: On the contrary, they think that the only justified attitude with respect to them is to disbelieve them—that is, they think that we are justified in believing that we do not know almost anything of what we take

ourselves to know. (When contemporary authors discuss skepticism, chances are they are referring to this aspect of Academic skepticism: to the claim that we do not know certain propositions that we ordinarily take ourselves to know. However, the tradition is to classify as a skeptic with respect to a certain proposition only someone who thinks we should suspend judgment with respect to that proposition, not someone who thinks that we should dissent from it.)

Pyrrhonian skeptics, meanwhile, extend their skepticism to epistemic propositions as well. Both Academic and Pyrrhonian skeptics leave it open whether Paris is the capital of France or not: maybe it is, maybe it is not, but we are not justified in believing that it is or believing that it is not. According to Pyrrhonian skeptics it is also an open question whether we know that Paris is the capital of France: maybe we do, maybe we do not, but we are not justified in believing that we do or that we do not. Academic skeptics, on the contrary, do not leave this question open: they think we are justified in believing that we do not know that Paris is the capital of France.

THE MODES OF AGRIPPA

From now on, the focus will be on Pyrrhonian skepticism exclusively. The Pyrrhonians had a number of ways, or modes, to induce suspension of judgment. The importance of Pyrrhonian skepticism to contemporary epistemology derives primarily from these modes, and in particular from a subset of them referred to collectively as the modes of Agrippa. There are five modes associated with Agrippa, but three of them are the most important: the mode of hypothesis (or unsupported assertion), the mode of circularity (reciprocal), and the mode of regression to infinity.

The three modes of Agrippa function together in the following way. Whenever the dogmatist (Sextus refers to those who are not skeptics as dogmatists) asserts his or her belief in a proposition p_1 , the Pyrrhonian will challenge that assertion, asking the dogmatist to justify p_1 , to give reasons for thinking that it is true. The dogmatist will then either decline to answer the challenge or adduce another proposition p_2 in support of p_1 . If the dogmatist refuses to answer the challenge, the Pyrrhonian will be satisfied that the only justified attitude to take with respect to p_1 is to suspend judgment, because no reason for it has been given (thus appealing to the mode of hypothesis). If the dogmatist adduces another proposition p_2 in support of p_1 , then either p_2 will be identical to p_1 or it will be a different proposition. If p_2 is the same proposition as p_1 , then the Pyrrhonian will also suspend

judgment with respect to p_1 , because no proposition can support itself (thus appealing to the mode of circularity). If, however, p_2 is different from p_1 , then the Pyrrhonian will ask the dogmatist to justify his or her assertion of p_2 . And now the dogmatist offers no reason in support of p_2 , offers p_2 itself or p_1 as a reason, or adduces yet another proposition p_3 , different from both p_1 and p_2 . If the dogmatist offers no reason for p_2 , then the Pyrrhonian will invoke the mode of hypothesis again and suspend judgment in accordance with it; if either p_2 itself or p_1 is offered as a reason to believe in p_1 , then the Pyrrhonian will invoke the mode of circularity and suspend judgment in accordance with it (because not only can no proposition be a reason for believing in itself but also no genuine chain of reasons can loop); and, finally, if the dogmatist offers yet another proposition p_3 , different from both p_1 and p_2 , as a reason to believe p_2 , then the same three possibilities that arose with respect to p_2 will arise with respect to p_3 .

The dogmatist will not be able to continue offering different propositions in response to the Pyrrhonian challenge forever—eventually, either no reason will be offered, or a proposition that has already made an appearance will be mentioned again. The Pyrrhonian refers to this impossibility of actually offering a different proposition each time a reason is needed as the mode of infinite regression. The three Pyrrhonian modes, then, work in tandem to induce suspension of judgment with respect to any proposition whatsoever.

AGRIPPA'S TRILEMMA

The Pyrrhonian use of the three modes of Agrippa to induce suspension of judgment can be presented in the form of an argument, called Agrippa's trilemma. It is at least somewhat misleading to present the Pyrrhonian position in terms of an argument, because in presenting an argument one is usually committed to the truth of its premises and conclusion, whereas Pyrrhonian skeptics would suspend judgment with respect to them. Nevertheless, presenting the Pyrrhonian problematic in the form of an argument does not do much violence to this skeptical position, because what is important is not whether the Pyrrhonian skeptics themselves accept the premises or the validity of the argument, but whether their audience does. Problems still remain regarding the coherence of anyone (be they Pyrrhonian skeptics or not) who accepts the soundness of an argument whose conclusion is that we are not justified in believing anything. It is doubtful, though, whether anyone accepts Agrippa's trilemma: "Dogmatists" certainly do not, and neither do Pyrrhon-

ian skeptics. It is not a coincidence that Wittgenstein's dictum about throwing the ladder after using it to climb echoes Sextus's less-pleasing image of the laxative that purges itself together with the "humours" of the body it is designed to expel. Still, even if we do not think that the argument is sound, we stand to learn something interesting about the structure of an epistemological theory—because each of the premises of the apparently valid argument looks plausible at first sight.

Before presenting a reconstruction of Agrippa's trilemma some definitions need to be introduced. Say that a belief is inferentially justified if and only if it is justified (at least in part) in virtue of its relations to other beliefs. A justified basic belief, by contrast, is a belief that is justified but not in virtue of its relations to other beliefs. An inferential chain is a set of beliefs such that every member of the set is allegedly related to at least one other member by the relation is justified by. Agrippa's trilemma, then, can be presented thus:

- (1) If a belief is justified, then it is either a basic justified belief or an inferentially justified belief.
- (2) There are no basic justified beliefs.

Therefore,

- (3) If a belief is justified, then it is justified in virtue of belonging to an inferential chain.
- (4) All inferential chains are such that either (a) they contain an infinite number of beliefs; (b) they contain circles; or (c) they contain beliefs that are not justified.
- (5) No belief is justified in virtue of belonging to an infinite inferential chain.
- (6) No belief is justified in virtue of belonging to a circular inferential chain.
- (7) No belief is justified in virtue of belonging to an inferential chain that contains unjustified beliefs.

Therefore,

- (8) There are no justified beliefs.

Premise (1) is beyond reproach, given our previous definitions. Premise (2) is justified by the mode of hypothesis. Step (3) of the argument follows from (1) and (2). Premise (4) is also beyond reproach—the only remaining possible structure for an inferential chain to have is to contain basic justified beliefs, but there are none of those according to premise (2). Premise (5) is justified by appeal to the mode of infinite regression, and (6) is justified by appeal to the mode of circularity.

Premise (7) might seem to be a truism, but some authors have argued that denying it is the only plausible way out of Pyrrhonian skepticism.

It is interesting to note that Agrippa's trilemma is perfectly general; in particular, it applies to philosophical positions as well as to ordinary propositions. In fact, when Agrippa's trilemma is applied to epistemological theories themselves, the result is called "the problem of the criterion."

Many contemporary epistemological positions can be stated as a reaction to Agrippa's trilemma. In fact, all of premises (2), (5), (6), and (7) have been rejected by different philosophers at one time or another. In the remainder of this entry, we examine each of these responses.

REJECTING PREMISE (2): FOUNDATIONALISM

Foundationalists claim that there are basic justified beliefs—beliefs that are justified but not in virtue of their relations to other beliefs. In fact, according to foundationalists all justified beliefs are either basic beliefs or are justified in virtue of being inferentially related to a justified belief (or to some justified beliefs). This is where foundationalism gets its name: The edifice of justified beliefs has its foundation in basic beliefs.

But how do foundationalists respond to the mode of hypothesis? If a belief is not justified by another belief, then is it not just a blind assertion? If basic beliefs are justified but not by other beliefs, then how are they justified? What else besides beliefs is there that can justify beliefs?

To this last question, many foundationalists reply: experience (if they are talking about empirical knowledge, of course; *a priori* knowledge raises interesting problems of its own, and it is also subject to Agrippa's trilemma). To a rough first approximation that glosses over many important philosophical issues, experiences are mental states that, like beliefs, aim to represent the world as it is, and, like beliefs, can fail in achieving that aim—that is, experiences can misrepresent. Nevertheless, experiences are not to be identified with beliefs, for it is possible to have an experience as of, for example, facing two lines that differ in length without having the belief that one is facing two lines that differ in length—a combination of mental states that anyone familiar with the Müller-Lyer illusion will recognize.

There are three important questions that any foundationalist has to answer. First, what kinds of beliefs do experiences justify? Second, how must inferentially acquired beliefs be related to basic beliefs for them to be

justified? Third, in virtue of what do experiences justify beliefs?

TRADITIONAL AND MODERATE FOUNDATIONALISM. With respect to the first question, we can distinguish between traditional foundationalism and moderate foundationalism. Traditional foundationalists think that basic beliefs are beliefs about experiences, whereas moderate foundationalists think that experience can justify beliefs about the external world. Take, for example, the experience that you typically have when looking at a tomato under good perceptual conditions—an experience that, remember, can be had even if no tomato is actually there. A moderate foundationalist would say that that experience justifies you in believing that there is a tomato in front of you. The traditional foundationalist, however, would say that the experience justifies you only in believing that you have an experience as of a tomato in front of you. You may well be justified in believing that there is a tomato in front of you, but only inferentially.

A traditional argument in favor of traditional foundationalism relies on the fact that whereas you can be mistaken regarding whether there is a tomato in front of you when you have an experience as of facing a tomato, you cannot, in the same situation, be mistaken regarding whether you are undergoing such an experience. From the point of view of traditional foundationalism, this fact indicates that the moderate foundationalist is taking an unnecessary epistemic risk—the risk of having a foundation composed of false beliefs.

The moderate foundationalist can reply that the traditional foundationalist must undertake a similar risk. For, while it is true that if one is undergoing a certain experience then one cannot be mistaken in thinking that one is undergoing that experience, one can still be mistaken about one's experiences—for instance, perhaps one can believe that one is in pain even if the experience that one is undergoing is actually one of feeling acutely uncomfortable. And if it were just as difficult to distinguish between the true and the false in the realm of beliefs about our own experiences as it is in the realm of beliefs about the external world, then we could be wrong about which of our own beliefs are basically justified and which are not. If this kind of metafallibilism is accepted, then why not accept the further kind according to which basic justified beliefs can be false? Of course, the resolution of this dispute depends on whether, as the moderate believes, we can be mistaken about our own experiences.

DEDUCTIVIST AND NONDEDUCTIVIST FOUNDATIONALISM. What about our second question: How must basic beliefs be related to inferentially justified beliefs? Here, too, there are two different kinds of foundationalism: deductivism and nondeductivism. According to the deductivist the only way in which a (possibly one-membered) set of basic justified beliefs can justify another belief is by logically entailing that other belief. In other words, there has to be a valid argument whose premises are all basic justified beliefs and whose conclusion is the inferentially justified belief in question. Given that the argument is valid, the truth of the premises guarantees the truth of the conclusion—it is impossible for all the premises to be true while the conclusion is false. Nondeductivism allows relations other than logical entailment as possible justificatory relations. For instance, many foundationalists will claim that good inductive inferences from basic justified beliefs provide their conclusions with justification—even though inductive arguments are not valid, that is, even though it is possible for all the premises of a good inductive argument to be true while its conclusion is false. Although these are independent distinctions, traditional foundationalists tend to be deductivists, whereas moderate foundationalists tend to be nondeductivists. Notice that for a traditional, deductivist foundationalist, there cannot be false justified beliefs. Many contemporary epistemologists would shy away from this strong form of infallibilism and take that consequence to be an argument against the conjunction of traditional foundationalism and deductivism.

PRIMITIVIST, INTERNALIST, AND EXTERNALIST FOUNDATIONALISM. The question that is most interesting from the point of view of the Pyrrhonian problematic is our third one: What is it about the relation between an experience and a belief that, according to the foundationalist, allows the former to justify the latter? (Analogous questions apply to nonfoundationalist positions too, and the discussion to follow is not restricted to the specific case of foundationalism.) There are three different proposals about how to answer this question that are the most prominent. The principles that assert that a subject is justified in having a certain belief given that he or she is undergoing a certain experience can be called epistemic principles. Our third question can then be stated as follows: What makes epistemic principles true?

The first proposal, which we shall call primitivism, claims that the question cannot have an intelligible answer. There is no more basic fact in virtue of which epistemic principles obtain. They describe bedrock facts, not to be explained in terms of anything else, but are

instead to be used to explain other facts. Epistemological theorizing, according to the primitivist, ends with the discovery of the correct epistemic principles.

The other two positions are nonprimitivist. Internalist nonprimitivism holds that epistemic principles are true in virtue of facts about ourselves—for instance, one prominent internalist view is that which epistemic principles are true for a given subject is determined by which epistemic principles that subject would accept under deep reflection. Externalist nonprimitivism holds that epistemic principles are true in virtue of facts that are not about ourselves—for instance, one prominent externalist view is that certain experiences provide justification for certain beliefs because the obtaining of those experiences is reliably connected to the truth of those beliefs (reliabilism), or because i.e., it could not easily happen that those experiences obtain without those beliefs being true (an appeal to “sensitivity” or “safety” conditionals).

Both externalists and internalists think that primitivists are overlooking real facts, whereas primitivists think that there are fewer things in heaven and earth than are dreamt of in nonprimitivist philosophy. Within the nonprimitivist camp externalists think that internalists have too subjective a conception of epistemology—to some extent, thinking it so, or being disposed to think it so under conditions of deep reflection, makes it so for at least some traditional internalists. Internalists, for their part, are likely to think that externalists are no longer engaged in the same project that both skeptics and internalist epistemologists are engaged in, the project of determining “from the inside” whether one’s beliefs are justified or amount to knowledge, because the obtaining of a relation between a subject’s belief and the external world is something that the subject is in no position to ascertain “from the inside.”

REJECTING PREMISE (5): INFINITISM

Infinetism, the claim that infinite evidential chains can provide justification to their members, is the answer to Agrippa’s trilemma that has received the least attention in the literature. This is due, at least in part, to the fact that infinitism has to deal with what might seem like formidable obstacles. For instance, it seems that no one actually has an infinite number of beliefs. To this objection, the infinitist is likely to reply that actually occurring beliefs are not needed, only implicit beliefs that are available to the subject to continue constructing his or her inferential chain if called on to do so (by others or by him- or herself). The plausibility of this reply depends on whether good sense can be made of the notion of implicit belief

and the notion of an implicit belief’s being available for a subject.

Even leaving that problem aside, the infinitist, like the coherentist, maintains that justification can arise merely in virtue of relations among beliefs. Infinitists will then have to respond to many of the same objections that are leveled against coherentism—in particular, they would have to respond to the isolation objection mentioned in the next section.

REJECTING PREMISE (6): COHERENTISM

Coherentists reject two related features of the picture of evidential reasons that underlies Agrippa’s trilemma. The first feature is the idea that justification is an asymmetrical relation: if a belief p_1 justifies a different belief p_2 , then p_2 does not justify p_1 . The second feature is the idea that the unit of justification is the individual belief. Putting these two rejections together, the coherentist believes that justification is a symmetrical and holistic matter. It is not individual beliefs that are justified in the primary sense of the word, but only complete systems of beliefs—individual beliefs are justified, when they are, in virtue of belonging to a justified system of beliefs. The central coherentist notion of justification is best taken to be a comparative one: A system of beliefs B1 is better justified than a system of beliefs B2 if and only if B1 has a greater degree of internal coherence than B2. One crucial question that coherentists have to answer, of course, is what it takes for one system of beliefs to have a greater degree of coherence than another. Many coherentists have thought that explanatory relations will be crucial in elucidating the notion of coherence: The more explanatorily integrated a system is, the more coherence it displays.

The main objection that coherentists have to answer is called the isolation objection. The objection centers on the fact that, according to the coherentist, the justification of a system of beliefs is entirely a matter of relations among the beliefs constituting the system. But this runs against the strong intuition that experience has an important role to play in the justification of beliefs. To illustrate the problem, suppose that you and I both have a highly coherent set of beliefs—your system, it is safe to assume, contains the belief that you are reading, whereas mine does not, and it contains instead the belief that I am swimming (because, let us suppose, I am swimming right now). Suppose now that we switch systems of beliefs—somehow, you come to have my set of beliefs and I come to have yours. Given that coherence is entirely a matter of relations among beliefs, your system will be as coherent in

my mind as it was in yours, and vice versa. And yet, our beliefs are now completely unjustified—there you are, reading, believing that you are swimming, and here I am, swimming, believing that I am reading. In other words, certain transformations that preserve coherence in a system of beliefs do not seem to preserve justification.

In reply, coherentists argue that it is possible to give experience a role without sacrificing the idea that justification is entirely a matter of relations among beliefs—one idea is to require that any minimally acceptable system of beliefs contain beliefs about the experiences that the subject is undergoing. It is fair to say that there is no agreement regarding whether this move can solve the problem.

REJECTING PREMISE (7): POSITISM

One position that can be traced back to some ideas in Ludwig Josef Johann Wittgenstein's *On Certainty* (published posthumously in 1969)—and, perhaps, also to José Ortega y Gasset's *Ideas y Creencias* (1940)—is that evidential chains have to terminate in beliefs that are not properly said to be either justified or unjustified. This position, which we shall call positism (not to be confused with positivism), shares many features with foundationalism: for instance, both positists and foundationalists agree that inferential chains have to be finite and noncircular. But, whereas the foundationalist thinks that the starting points of inferential chains are beliefs that are justified by something other than beliefs, the positist thinks that the starting points of inferential chains are beliefs that are not justified by anything—they are posits that we have to believe without justification. Despite this difference between the positist and the foundationalist, the positions are structurally similar enough that analogues of the questions posed to the foundationalist can be asked of the positist.

First, then, which beliefs are such that they are not justified and yet are the starting points of every inferential chain—in other words, how do we identify which are the posits? One answer that can be gleaned from Wittgenstein's *On Certainty*, which we will call relativistic positism, is that this is a matter that is relative both to time and society, because what the posits are is determined by some function of the actual positing practices of the members of one's society at a certain time. Thus, according to Wittgenstein the proposition that no one has been to the moon was a posit for a certain long period of time—it was a proposition that no one felt the need to justify, and that was presupposed in many justificatory practices. For obvious reasons, though, that proposition

can no longer appropriately function as a posit. Other epistemologists, nonrelativistic positists, think that which beliefs are properly posited depends on some objective truth about which beliefs have to be presupposed to engage in the practice of justifying beliefs at all. One prime candidate for playing this role is the first-person belief that I am not being deceived by an evil demon into thinking that I am a normally embodied and situated human being.

The second question, regarding how posits must be related to inferred beliefs to justify them, can receive answers that are completely analogous to the foundationalists'. The third question, applied to positism, is the question why certain beliefs are properly posited. Relativistic positists answer that this is so because of a certain societal fact: because they are taken to be so by an appropriate subsector of a certain society at a certain time. Nonrelativistic positists answer that a certain belief is properly taken as a posit just in case every justificatory act that we engage in presupposes that the belief in question is true.

One objection that positists of both sorts have to face is that they are transforming a doxastic necessity into an epistemic virtue—that is, they are concluding that certain beliefs can properly serve as the starting points of inferential chains because that is how in fact they are treated (relativistic positism) or because otherwise it would not be possible to engage in inferential practices at all (nonrelativistic positism). The Pyrrhonian skeptic, of course, will reply that the mere fact that most members of a society accept a certain belief without justification, or even the fact that if we do not do so then we cannot justify anything else, does not mean that it should be accepted without justification.

CONCLUSION

Perhaps one of the most interesting developments in relation to the Pyrrhonian problematic is that more and more epistemologists are arguing that the proper way to reply to Agrippa's trilemma is to combine some of the positions that, for ease of exposition, we have presented as mutually exclusive (this development is explicit in contemporary authors such as Sosa, but, some will argue, it is already present in Descartes). Thus, for example, many contemporary epistemologists put forward theories that contain elements of both internalism and externalism, or foundationalism and coherentism. It is a testament to the endurance of the Pyrrhonian problematic that philosophers continue in this way to grapple with it.

PYTHAGORAS AND PYTHAGOREANISM

Pythagoras was an Ionian Greek born on the island of Samos, probably about 570 BCE. His dislike of the policies of the Samian tyrant Polycrates caused him to immigrate to Crotona in southern Italy. There he founded a society with religious and political, as well as philosophical, aims that gained power in the city and considerably extended its influence over the surrounding area. A certain Cylon, however, stirred up a revolt against the society in which a number of its leading members were killed, and Pythagoras retired to Metapontum. The community recovered its influence until a more serious persecution took place in the middle of the fifth century, from which the survivors scattered to various parts of the Greek

world—notably Thebes, Phleius, and Tarentum. In these places "they preserved their original ways and their science, although the sect was dwindling, until, not ignobly, they died out" (in the late fourth century), to quote the epitaph written by a contemporary.

NATURE OF THE EVIDENCE

The obstacles to an appraisal of classical Pythagoreanism are formidable. There exists no Pythagorean literature before Plato, and it was said that little had been written, owing to a rule of secrecy. Information from the Christian era is abundant but highly suspect. Pythagoras himself, though a fully historical figure, underwent a kind of canonization. His life was quickly obscured by legend, and piety attributed all the school's teaching to him personally. Moreover, the dispersion of the school inevitably led to divergences of doctrine in the various groups. Aristotle makes it clear that by the late fifth century some Pythagoreans were teaching one thing and some another. A further reason for division was that the universal genius of Pythagoras, for whom religion and science were two aspects of the same integrated worldview, was beyond the scope of lesser men. Some naturally inclined more to the religious and superstitious; others, to the intellectual and scientific side, as is confirmed by later references to the division between *acusmatici* and *mathematici*.

As early evidence there are several references to Pythagoras in works of his contemporaries or near contemporaries (for instance, Xenophanes satirized his belief in the transmigration of souls), a valuable reference in Plato to the relationship between astronomy and harmonics in the Pythagorean system, a quantity of information from Aristotle (who at least would not confuse the Pythagoreans with Plato, as later writers excusably did), and some quotations from pupils of Aristotle who were personally acquainted with the last generation of the school.

Given the nature of the sources, the following is a fairly conservative summary of Pythagoreanism before Plato.

MAN AND THE COSMOS

In contrast with the Milesians, the Pythagoreans were not motivated by disinterested scientific curiosity. For Pythagoras, philosophy was the basis of a way of life, leading to salvation of the soul. "Their whole life," said a fourth-century writer, "is ordered with a view to following God, and it is the governing principle of their philosophy." At philosophy's center, therefore, were man and his relation to other forms of life and to the cosmos. Purity

was to be sought by silence, self-examination, abstinence from flesh and beans, and the observance of other primitive taboos that the Pythagoreans interpreted symbolically. Of the recognized gods they worshiped Apollo, guardian of the typically Greek ideal of moderation (“nothing too much”), of whom Pythagoras was believed to be an incarnation.

Behind both the superstition and the science was the notion of kinship or sympathy. The kinship and essential unity of all life made possible the belief in the transmigration of souls and accounted for the prohibition of meat: a sheep might house the soul of an ancestor. Not only animate nature in our sense but the whole world was akin, for the cosmos itself was a living, breathing creature. The cosmos was one, eternal, and divine; men were divided and mortal. But the essential part of man, his soul, was not mortal; it was a fragment of the divine, universal soul that was cut off and imprisoned in a mortal body. Men should therefore cultivate and purify the soul, preparing it for a return to the universal soul of which it was a part. Until then, since it was still contaminated by the body, it must tread the wheel of reincarnation, entering a new body of man or animal after the death of its previous tenement.

These tenets were also taught by the religious movement known as Orphism, from which the religious side of Pythagoreanism can hardly be separated. (Pythagoras himself was said in the fifth century to have written books under the name of Orpheus.) But whereas the Orphics sought salvation by purely religious means—sacramental ceremonies and the observance of ritual prohibitions—Pythagoras added a new way, the way of philosophy.

Philosophy, for Pythagoras as for others, meant the use of reason and observation to gain understanding of the universe. The link between this procedure and his overriding aim of salvation seems to have been the principle that like is known by like, a widespread tenet of pre-Socratic thought, common to such diverse systems as the philosophicoreligious synthesis of Empedocles and the scientific atomism of Democritus. Hence, an understanding of the divine universe would bring man’s nature closer to its own. In this conception we meet the typically Pythagorean conception of *kosmos*, a word that combines in an untranslatable way the notion of orderly arrangement or structural perfection with that of beauty. Closely linked with it is *peras*, meaning limit. An organic whole, particularly one that, like the universe, lives forever, must of necessity exhibit limit and order in the highest degree. What is unlimited has no *telos* (end) and is *a-teles*, which means both “endless” and “incomplete.” But the world is

a perfect whole, a model of order and regularity, supremely exemplified in Greek eyes by the ceaseless wheeling of the heavenly bodies in (as they believed) perfect circles, bringing about the unvarying succession of day and night and seasons. It was said of Pythagoras that he was the first to call the world *kosmos*, “from its inherent order.” By studying this order, we reproduce it in our own souls, and philosophy becomes an assimilation to the divine, as far as that is possible within the limitations imposed by our mortal bodies.

THE DOCTRINE THAT THINGS ARE NUMBERS

The Pythagoreans studied mathematics in a cosmic context, and for them numbers always retained a mystical significance as the key to the divine cosmos. “They supposed the whole heaven to be a *harmonia* and a number,” said Aristotle. *Harmonia*, though specially applied to music, could signify any well-organized structure of parts fitted together in due proportion. Its effect in music seems to have burst on Pythagoras as a revelation of the whole cosmic system. We may accept the many later statements that he discovered the numerical ratios underlying the intervals that the Greeks called consonant and used as the basis of their scale. They involve only the numbers 1 to 4—1:2, octave; 3:2, fifth; 4:3, fourth. These numbers add up to 10, a sacred number for the Pythagoreans, which was symbolized by the dotted triangle (*tetractys*), “source and root of everlasting nature.” From the discovery that the sounds they recognized as beautiful depended on inherent, objective, mathematical order, they leaped to the conclusion that number was the key to the element of order in nature as a whole.

With this innovation the Pythagoreans would seem to have taken the momentous step from explanation in terms of matter (as the Milesians had sought it) to explanation in terms of form. Yet philosophy was not quite ready for that step, nor could the distinction between matter and form be clearly grasped. They saw simply the ultimate, single nature (*physis*) of things in their mathematical structure. There seems little doubt that probably until well on in the fifth century they thought it possible to speak of things as actually made up of “numbers” that were regarded simultaneously as units, geometrical points, and physical atoms. Lines are made of points; surfaces, of lines; solids, of surfaces; and physical bodies, of solids. In this scheme two points made a line; three, the minimum surface (triangle); four, the minimum solid (tetrahedron). A later theory spoke of the “fluxion” of point into line, line into surface, and so on, which gave a

geometrical progression (1, 2, 4, 8) instead of the arithmetical (1, 2, 3, 4), and the sequence of point, line, square, cube. Based on continuity, it seems designed to avoid the problem of incommensurable magnitudes or irrational numbers.

Whenever they were discovered (probably not much later than 450), incommensurables had dealt a blow to the original “things are numbers” doctrine, the idea that geometrical figures—and thus ultimately the physical world—are based on a series of integers. No ratio between integers can either describe the relation between the diagonal of a square and its side or serve as the basis of construction of a right triangle. If, however, magnitudes are regarded as continuous and hence infinitely divisible, the existence of incommensurable or irrational magnitudes (those which cannot be expressed as a ratio of natural numbers) could be explained and the difficulty overcome.

THE ULTIMATE PRINCIPLES

The analysis went further than that outlined above, for numbers themselves have their elements. The ultimate principles were limit and the unlimited, which were equated with good and bad respectively; moral concepts went side by side with physical concepts in this extraordinary system. Abstractions as well as physical phenomena were equated with numbers; for instance, justice was 4, the first square number, symbolizing equality or requital. After limit and the unlimited came odd and even instances, respectively, of these two. They generated the unit (considered to be outside the number series, and both odd and even), from the unit sprang numbers, and from numbers came the world. There seems no doubt that the scheme goes back to an ultimate duality that corresponds to the moral dualism of Pythagoreanism, but one can also see how monistically minded Neoplatonic commentators could speak of the cosmos as originating from the One. In general terms, *kosmos* was achieved by the imposition of limit on the unlimited in order to make the limited, just as the imposition of definite ratios on the indefinite range of musical pitch produced the *harmonia* of the scale.

COSMOGONY AND COSMOLOGY

Cosmogony starts with the planting of a unit in the infinite. Aristotle called it, among other things, a seed; and since limit was associated with male and unlimited with female, the Pythagoreans probably thought of the generation of the living cosmos as taking place as did that of other animals. It grows by drawing in and assimilating the

unlimited outside, that is, by conforming it to limit and giving it numerical structure. Physically the process resembles inspiration, and the unlimited is also called breath.

The unit seed had the nature of fire and in the completed cosmos (which evidently grew from the center outward) became a fire at its center. There are traces of two different cosmological schemes, a geocentric one that spoke of a fire at the center of Earth, and a more remarkable one attributed, in later sources at least, to the fifth-century Pythagorean Philolaus, which made Earth a planet. (Nicolas Copernicus in *De Revolutionibus* says that reading of this Pythagorean doctrine gave him courage to consider explaining the heavenly motions on the basis of a moving Earth.) According to this latter scheme, Earth, planets, sun, and moon—and an extra body called the counterearth—all revolved about the center of the universe, which was occupied by a fire invisible to man because he lived on the opposite side of Earth. It was known that the moon’s light is borrowed, and the idea was extended to the sun, whose heat and light were said to be reflected from the central fire. The moon was eclipsed by the interposition of both Earth and the counterearth and, according to some, of further, otherwise unknown, planetary bodies. These caused the comparatively frequent lunar eclipses.

In this system, the mixture of religion and science in Pythagoreanism is well brought out. Fire was given the central position, not for any scientific reason but because it was regarded with religious awe—and the center is the most “honorable” place. It was lauded with such titles as Hearth of the Universe, Tower of Zeus, and Throne of Zeus. Yet the same thinkers were aware that with Earth in orbit “the phenomena would not be the same” as in a geocentric scheme (presumably they were thinking of the lack of stellar parallax and variations in the apparent size of the sun and moon). They pointed out that even with a central Earth, an observer would be separated from the center by the distance of its radius, and they argued that the visible effect would be as negligible in one case as in the other. This assumes that the heavenly bodies are at vast distances from Earth; and it is not known how, if at all, this system was related to the theory later known as the harmony of the spheres.

In any case, there are many divergent versions of this doctrine. In outline, the idea was that large bodies in motion must inevitably produce a sound; that the speeds of the heavenly bodies, judged by their distances, are in the ratios of the musical consonances; and that therefore the sound made by their simultaneous revolution is con-

cordant. We do not hear it because it has been with us from birth, and sound is perceptible only by contrast with silence. It has been plausibly argued that in the original version Pythagoras, like Anaximander, took only three orbits into account (sun, moon, and all the stars); this would relate it to his original musical discovery about the fourth, fifth, and octave. Later versions speak of seven, eight (Plato), and ten orbits. In any form, the doctrine emphasizes the universal importance, in Pythagorean eyes, of mathematical and musical laws and their intimate relation to astronomy.

NEO-PYTHAGOREANISM

The influence of Pythagorean thought on the history of philosophy and religion has been exercised largely through the medium of Plato, who enthusiastically adopted its main doctrines of the immortality of the soul, philosophy as an assimilation to the divine, and the mathematical basis of the cosmos. Later antiquity regarded him as a Pythagorean source, so that post-Platonic writings are of little help in distinguishing Pythagorean from original Platonic material in the dialogues. The Neo-Pythagorean movement, which started in the first century BCE, was an amalgam of early Pythagorean material with the teachings of Plato, the Peripatetics, and the Stoics. All of this material was credited to Pythagoras, who was revered as the revealer of esoteric religious truths. The interests of Neo-Pythagoreanism were religious and, in accordance with the prevailing tendencies of the time, it emphasized the mystical and superstitious sides of the earlier doctrine, its astral theology and number-mysticism, to the detriment of philosophical thinking. It cannot be called a system, but rather is a trend that in different forms continued until the rise of Neoplatonism in the third century CE, when it lost its identity in that broader and more powerful current. Besides contributing to Neoplatonism, it influenced Jewish thought through Philo of Alexandria and Christian thought through Clement of Alexandria. Prominent Neo-Pythagoreans were Cicero's acquaintance, Nigidius Figulus, and Apollonius of Tyana, a wandering mystic and ascetic of the first century CE, credited with miraculous and prophetic powers. Numenius of Apamea in the late second century was called both Pythagorean and Platonist, and was the immediate precursor of Neoplatonism.

W. K. C. Guthrie (1967)

PYTHAGORAS AND PYTHAGOREANISM [ADDENDUM 1]

Scholarship on Pythagoras and early Pythagoreanism has undergone a revolutionary change in recent decades. On the one hand, we know much less about Pythagoras and the early school than seemed to be the case a generation ago. On the other hand, it is no longer true that, as W. K. C. Guthrie writes in the original article above, "there is no Pythagorean literature before Plato." Both changes are due to the work of Walter Burkert (1962/1972).

THE NEW SKEPTICISM ABOUT EARLY PYTHAGOREAN PHILOSOPHY

There had always been skeptics who doubted the traditional view of scientific work by Pythagoras and his early followers. Burkert showed decisively how far this tradition derived from a completely unhistorical view of

Pythagoras created in Plato's Academy and popularized by Plato's immediate successors. The striking similarities between Plato's work and the traditional account of Pythagorean philosophy (as given in Guthrie's article) are largely due to this post-Platonic tradition, which in later versions regularly credited Pythagoras with the invention of Platonic philosophy. At the same time, Burkert defended the authenticity of most of the fragments attributed to Philolaus (in the middle or late fifth century BCE), which are now generally recognized as the earliest Pythagorean texts.

Except for the fragments of Philolaus and a single reference in Plato (reporting that the Pythagoreans regarded music and astronomy as "sister sciences" [*Republic* 530d]), there is no account of Pythagorean philosophy before Aristotle. Furthermore, there is no evidence of any Pythagorean writing before Philolaus. So Aristotle, writing a century and a half after Pythagoras's death, was entirely dependent on an oral tradition for information about the teachings of the early pre-Philolaus school. Since Pythagoras became a figure of legend almost in his own lifetime, it is extremely difficult to know how much of Aristotle's account can be traced back to the founder or to his early followers. We do have some early references to Pythagoras, notably by Heraclitus, but these references are hostile and open to diverse interpretations.

PYTHAGOREAN PHILOSOPHY DOWN TO THE TIME OF PLATO

There is no fully reliable account of early Pythagorean doctrine. All we know for certain is that he advocated some version of reincarnation, since Xenophanes, a contemporary, makes fun of Pythagoras for the belief that a human psychē could be reborn in an animal body. Good sources report that Pythagoras founded a cult society or sect, with special dietary restrictions (ultimately including vegetarianism), whose members played an important political role in the cities of southern Italy for several generations. Burkert regarded Pythagoras as essentially a religious teacher, a charismatic guru who founded a ritual community without scientific or philosophic content. Philolaus in the late fifth century then appears as the first Pythagorean philosopher. This interpretation has been followed by many scholars, including the influential study *Philolaus of Croton* by Carl Huffman (1993). On the other hand, the surviving fragments of Philolaus do not show him to be a profoundly original thinker, and some scholars (including the present author) would regard Philo-

laus as formulating, and perhaps updating, an older Pythagorean world view.

The references by Heraclitus to Pythagoras as a polymath who "pursued inquiry further than anyone else" suggest that the more archaic features of this world view go back to the founder himself. As a native of Samos, Pythagoras may well have absorbed the new naturalistic cosmology being worked out in neighboring Miletus during his lifetime. The musical elements in the Pythagorean scheme would then be the personal contribution of Pythagoras himself. It is probably from this school that Plato has taken the notion of the music of the spheres, the cosmic harmony produced by the movement of the heavenly bodies. The numerical proportions corresponding to the musical consonances (2:1, 3:2, 4:3) are embedded in the Sacred Tetractys, the number 10 as the sum of 1+2+3+4, said to be the source of natural order and to provide the oath "by which the Pythagoreans swear." (Diels-Kranz, *Fragmente der Vorsokratiker* 58.B 15) Teachings of this kind may well go back to the first generation in the sixth century. The reports concerning Hippasus of Metapontum (probably dated in the early fifth century) indicate that an interest in the harmonic mean is older than Philolaus. How much work in mathematics or astronomy can be attributed to the early Pythagoreans is another question. But at least one contemporary scholar (Leonid Zhmud 1997) has argued in favor of the traditional view of Pythagoras as founder of a scientific school.

Aristotle reports that the Pythagoreans were pioneers in mathematics and interpreted the whole universe in terms of numbers. However, except for vague reports concerning Hippasus, we know nothing of Pythagorean mathematics in the early period. (The first author to refer to the "Pythagorean theorem" is Plutarch, in the Roman period.) Documentation for Pythagorean teaching begins with Philolaus. He claims that the *kosmos*, or world order, is composed of two opposing principles that are harmoniously fitted together, the principle of Limit or Limiting (*perainonta*) and the Unlimited (*apeiron*). The world is knowable because it is structured by number, and the numbers of special interest are the musical ratios: 2:1, 3:2, 4:3. Aristotle's report of a Pythagorean cosmology in which the earth is a planet like the sun, circulating around a central Fire, seems to be derived from Philolaus. The two Philolaic principles, the Limit and the Unlimited, show up in a famous passage in Plato's *Philebus*, Plato's dialogue, where they are said to have been tossed down from heaven, together with fire, by a certain Prometheus (*Philebus* 16c). Many readers have found it natural to

identify this Prometheus with Pythagoras. This passage may be one of the sources for the ancient story that Plato borrowed his philosophy from Pythagoras.

There is a kernel of truth in the myth that Plato's philosophy is Pythagorean. A genuinely Pythagorean view of the soul as transcending its existence in a human body serves as point of departure for Plato's *Phaedo*. A similar view of the soul is presupposed by the doctrine of recollection in the *Meno* and by the myths of judgment and preexistence in the *Phaedo*, *Republic*, and *Phaedrus*. Furthermore, the other typically Pythagorean view, the mathematical interpretation of nature and the conception of the cosmos in terms of musical harmony, finds its fullest expression in Plato's *Timaeus*. These two dialogues, the *Phaedo* and the *Timaeus*, form the channel through which Pythagorean ideas have passed into the mainstream of ancient and modern thought.

It is important, however, not to exaggerate Plato's debt to the Pythagorean tradition. In most cases, for instance in the judgment myths, Plato has probably transformed Pythagorean material beyond recognition. The pre-Platonic version would appear crude and primitive by comparison. This is perhaps clearest in the case of recollection. Plato's doctrine takes for granted the Pythagorean view of a cycle of reincarnation for the human psyche. But in the original Pythagorean version, recollection would refer only to Pythagoras' alleged ability to recall his previous incarnations, or perhaps to the soul's need to remember certain ritual instructions for correct behavior in the next world—the need to preserve a memory after death that avoids or survives the drink from the River Lethe (forgetfulness). The notion of recollection as a theory in epistemology, as a priori knowledge preceding sensory experience, is entirely Plato's invention. There is no Pythagorean epistemology, and nothing corresponding to the doctrine of Forms. Plato's theory of recollection represents an allegorical reinterpretation of Pythagorean themes that are originally magical or mythical.

In the case of mathematics, however, Pythagorean influence on Plato may be more substantial. The leading Pythagorean of Plato's day, Archytas of Tarentum, was both Plato's friend and also a great mathematician. Of course, not all the mathematics in Plato's dialogues needs to be derived from Pythagorean sources. (Theaetetus, for example, was not a Pythagorean, nor was his teacher Theodorus.) But Plato does cite the Pythagoreans for their view of the relation between music and astronomy (*Republic* 530d, in what is apparently a quotation from Archytas). Unfortunately, we are very poorly informed on

the details of Archytas's work in astronomy and applied mathematics. Hence we cannot tell to what extent his thought inspired Plato's use of geometrical figures and numerical proportions in the cosmology of the *Timaeus*. The role of musical harmonies in the creation of the world soul is at least Pythagorean in spirit. It was the cosmology of the *Timaeus* that became the model for a Pythagorean world view in later centuries, down to the time of Johannes Kepler.

PYTHAGOREANISM AFTER PLATO

Aristotle reports that among Plato's "unwritten doctrines" was a theory of two fundamental principles: the One and the Indeterminate Dyad. These principles are regularly attributed to Pythagoras in the post-Aristotelian doxography, together with a mathematical cosmology based on the *Timaeus*. This grandiose and completely unhistorical picture of Pythagorean philosophy, which was accepted throughout antiquity, seems to have been created by Plato's disciples in the Academy and, in particular, by Speusippus, Plato's successor as head of the school. Speusippus composed a book *On Pythagorean Numbers*, which is largely devoted to the cosmological implications of the number 10. This number generates all things by containing as parts the numbers 1, 2, 3, and 4, corresponding, respectively, to point, line, plane, and solid. Thus, Pythagorean numerology, the doctrine of the symbolical and allegorical significance of the numbers from 1 to 10, seems to have begun with Speusippus.

The personal prestige of Pythagoras remained high in the Hellenistic age, although the Pythagorean school seems to have died out by the end of the fourth century BCE. What we find instead are pseudepigraphic works, treatises claiming as their author was either Pythagoras himself or, more frequently, one of his followers. The most popular author for these forged books is Archytas, but there is also a work ascribed to Timaeus of Locri, the fictitious speaker in Plato's dialogue of that name. This treatise has been preserved intact because it was falsely believed to be the Pythagorean original from which Plato derived his cosmology. In general, these pseudepigraphic works contain doctrines borrowed from Plato and Aristotle, with little or no material that is authentically Pythagorean.

A more genuine Pythagorean revival begins in the first century BCE in Rome with a famous Roman magus named Nigidius Figulus, to whom Cicero dedicated his translation of the *Timaeus*. Combining Oriental lore with Greek wisdom and the gift of second sight, Nigidius seems to have created a kind of Pythagorean society

within the Roman aristocracy. The distinguished scholar Marcus Terentius Varro was attracted by this archaic cult, and Cicero himself showed great respect for the Pythagorean tradition. Pythagoras had always been popular in Rome. At the beginning of the third century BCE, in response to an oracle during the Samnite war, a statue of Pythagoras was erected in the Roman forum. The popularity of Pythagoras in Rome was due in part to the fact that the original Pythagorean community had been located in the Greek cities of southern Italy, and hence Pythagoreanism was known since Aristotle as the *Italian philosophy*. Since most philosophers were from Greece proper, the Romans were pleased to have their own sages from Croton, Metapontum, and Tarentum.

At the same time that Nigidius was reviving Pythagoreanism in Rome in the first century BCE, Eudorus of Alexandria was inaugurating a new line of Platonic philosophers who have come to be called the Neopythagoreans. The name reflects the fact that these philosophers share the view that Plato's philosophy was derived from Pythagoras. Thus, Eudorus reports that "Socrates and Plato agree with Pythagoras that the goal of life (the *telos*) is becoming like god. But Plato articulated it more clearly by adding 'as far as possible.'" (Plato, *Theaetetus* 176b.) In reaction against the tradition of Skepticism that prevailed in the Hellenistic Academy, these philosophers emphasize the metaphysical and theological elements in Plato's philosophy. In this respect, and in the central importance attributed to numbers, the Neopythagoreans return to a position like that of Speusippus and Xenocrates in the Old Academy.

According to Eudorus, the Pythagoreans regard the One as the first principle of all things and the supreme god, but immediately below it are the two opposed principles, the One and the Indefinite Dyad. This notion of a hierarchical system of transcendental principles was developed in a new version of Pythagorean philosophy by Moderatus of Gades in the first century CE. Here there are three levels of nonsensible reality represented by three Ones. (The three Ones are related to the first three hypotheses in Plato's *Parmenides*.) Other Platonists in this tradition refer to a doctrine of three gods as distinctively Pythagorean. The best-preserved view is that of Numenius of Apamea in the second century CE. The first god is pure *nous*, an intellect focussed only on itself, like Aristotle's Prime Mover; the second god is *nous* as the demiurge, responsible for ordering the material universe; the third god is either the visible cosmos or its animating principle, the world soul. There is a significant parallel between this tripartite scheme and the three hypostases of

Plotinus (the One, the Intellect, and the Soul), and it is not surprising to learn that Plotinus was accused of borrowing his philosophy from Numenius.

Pythagorean influence continued into late antiquity and the middle ages, both as numerology and as integrated into Neoplatonism, above all in the work of Iamblichus (c. 300 CE), who composed a book *On the Pythagorean Way of Life* as an introduction to his major work *On the Pythagorean School*. Pythagorean harmonics (through the influence of Boethius) continued to play a role in music down to the modern age. Finally, in the Renaissance, Pythagorean ideas were revived with the new access to Plato and the Neoplatonists. This leads, on the one hand, to a flowering of occult numerology and theosophy—for example, in the cosmology of Robert Fludd—and on the other hand, to scientific applications of Pythagorean thought in the work of Copernicus and Kepler. It was Kepler who made the last great scientific contribution to the Pythagorean tradition. Taking as his model the *Timaeus* and Ptolemy's *Harmonica*, Kepler published his laws of planetary motion in a work titled *Harmonice Mundi* (The harmonics of the universe), in which he undertook to show how the movements of the planets were designed to illustrate the Pythagorean music of the spheres. Kepler's work brings the story of scientific Pythagoreanism to a happy conclusion. In one sense, the spirit of Pythagoreanism is still alive today in the mathematical interpretation of nature; string theory may be the latest version of the harmony of the spheres.

PYTHAGORAS AND PYTHAGOREANISM [ADDENDUM 2]

Ideas of Pythagoras and his school (including Philolaos) became known to the Islamic and to a lesser degree to the Jewish world since the end of the ninth century. Doxographical information about them can be found in Arabic translations of Aristotle, Plato, and above all two doxographical sources: the *Placita philosophorum*, which is attributed to Plutarch and is assumed to be compiled by Aetius Arabus (Daiber 1980), and a doxography that is attributed to Ammonius and is available only in an Arabic version (Rudolph 1989), much like the Arabic translation of the *Placita* apparently from the second half of the ninth century.

The impact of these sources, especially of Aetius, on Islamic thought (Rosenthal 1965, Daiber 1980), p. 337f.), on the Islamic philosopher al-Kindī, who died in 866 (Baffioni 1985), on the anonymous encyclopaedia of the Sincere Brethren from the tenth century (Netton 1991), and on the Jewish philosopher Sa'adia ben Joseph in the first half of the tenth century (Efros), was concentrated on the Pythagorean doctrine of numbers, especially of the number four as source of the cosmos and its harmony, and also applied to music. Shahrastani's exposition of the Pythagorean doctrine (Baffioni 1983), pp. 96ff.), which mainly combined the reports of Aetius and in Ara-

bic doxography attributed to Ammonius (Rudolph 1989), shaped the picture of Pythagoras among Islamic thinkers.

Moreover, Neo-Pythagorean texts on ethics contributed to the propagation of Pythagorean thought in Islamic and Jewish circles. Here, an important role was played by the Pythagorean *Carmina aurea* on ethical principles of life such as piety, modesty, justice, and self-examination as ways of the soul's assimilation to God. This text was known to the Arabs in an anonymous Arabic translation from the second half of the ninth century, which was integrated in Ḥunayn ibn Ishāq's *Nawādir al-falāsifa* (Anecdotes of the Philosophers), a collection of wise sayings that was often used by Muslim authors (Baffioni 1994, Miskawayh 1964), and that in the adaptation of Muhammad ibn 'Alī al-Anṣārī was translated into Hebrew (Daiber 1995).

Originally, the *Carmina aurea* were translated into Arabic with the commentary by Iamblichus (250–330 CE), a pupil of the neoplatonic philosopher Porphyry. This commentary, which is lost in its Greek original and preserved in Arabic (Daiber 1995), differs from that attributed to Proclus, which in a similar manner offers Neo-Pythagorean traditions in neoplatonic shape and which is preserved in a redaction by Abū l-Faraj ibn al-Tayyib from the eleventh century (Linley 1984; cf. Daiber, *Islam* 65 1988, 134–137). Iamblichus's commentary continues the discussion of his *De vita pythagorica* and *Protrepticus* and amalgamates Pythagorean, Platonic-neoplatonic, Aristotelian, and Stoic ethics. It found an echo in al-Kindī, who in his "Summary on the Soul According to Aristotle, Plato, and Other Philosophers" describes the ascent and return of the soul to its divine origin through purification and increasing knowledge of God—a doctrine that is developed a century later in the encyclopaedia of the Sincere Brethren (Baffioni 1992) and is alluded to in Ibn Sīnā's (Avicenna) (d. 1037) alleged Pythagoreanism (Chaix-Ruy 1959).

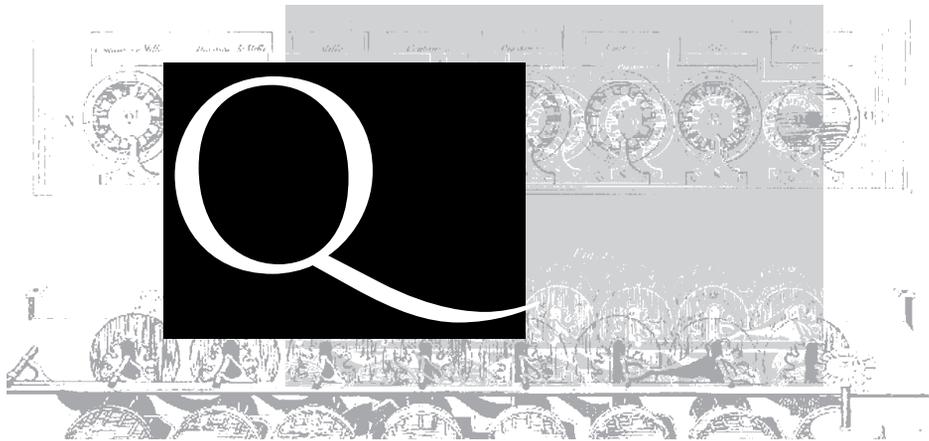

Iamblichus's neoplatonic tradition of the *vita pythagorica* is reflected in a treatise attributed to Plato, "The Exhortation concerning the Education of Young Men," which is preserved only in Arabic (Rosenthal 1941, pp. 383ff.). It can be traced back to his teacher, Porphyry, who in his *History of Philosophy* (lost in Greek and preserved in some Arabic fragments) had included the biography of Pythagoras (Rosenthal 1990). It seems plausible that the same neoplatonic tradition of the *vita pythagorica* also affected the alleged letter by Pythagoras to Hiero, the tyrant of Sicily, which is available in a clumsy ninth-century translation (Rosenthal 1975). Finally, Neo-Pythagorean ethics is mirrored in the numerous sayings

attributed to Pythagoras and transmitted in Syriac and Arabic gnomologia (Gildemeister 1870, Levi della Vida 1910, Gutas 1975).

Hans Daiber (2005)

QUALIA

The word *quale* (or *qualia*) derives from the Latin for “quality.” As used by C. I. Lewis (1929) and those following him, it refers to the qualities of phenomenal individuals, such as color patches, tastes, and sounds. In this sense the term means what George Berkeley meant by “sensible qualities,” or what later philosophers meant by *sensa* or *sense data*. Since the demise of sense data theories, the term *qualia* has come to refer to the qualitative, or phenomenal, character of conscious, sensory states, so that it is mental states, not phenomenal individuals, that are the subjects of predication. Another expression for this aspect of mental life is the “raw feel” of experience, or “what it’s like” to have certain sensory experiences. Qualia are part of the phenomenon of the subjectivity of consciousness, and pose one of the most difficult problems for a materialist solution to the mind-body problem.

IDENTITY THEORY

J. J. C. Smart posed the challenge this way in a 1959 article: Consider a sensation like a yellowy-orange after-image. According to the materialist theory known as the “central state identity theory” (or just “identity theory”), the sensation is a brain state. Smart’s worry, which he

attributed to Max Black, was that even if one accepted that the sensation was itself a brain state, it still seemed as if one had to attribute an “irreducibly psychic” property to the brain state. That is, there is a distinctive qualitative character experienced when having a yellowy-orange after-image, and that property—that yellowy-orange character—does not seem at all like a physical property. So even if all mental states are brain states, we might still be driven to the view that some mental properties—qualia, in particular—are not physical. This would constitute a form of dualism known as “property dualism,” a position inconsistent with materialism.

The Max Black objection presented by Smart in 1959 is related closely to the “conceivability argument,” a dualist argument going back to René Descartes, and revived in 1980 by Saul Kripke and in 1996 by David Chalmers. Roughly, the idea is this. When one considers simultaneously what it is like to see a yellowy-orange after-image and any description of the firing pattern of an assembly of neurons, it seems perfectly coherent to imagine having the one without the other. That neurons should fire in this or that pattern and that it should be like nothing at all for the subject whose neurons they are seems clearly possible. Yet, if qualia are identical to neural properties, such a situation is not possible. Hence, qualia must be not

neural properties, but nonphysical properties possessed by neural states.

Another closely related dualist argument is Frank Jackson's 1982 "knowledge argument." We are asked to imagine a scientist who knows everything about the physiology of color vision, but who has never seen anything in color. Upon first seeing a red rose, it seems clear that she would learn something new—what it is like to see red. Yet, if qualia are just physical properties of the nervous system, she should have already known what it is like to see red. Hence, Jackson concludes, qualia are not physical properties.

Many materialist philosophers object that these dualist arguments rely on an assimilation of concepts and properties. Concepts are elements of thought, ways of thinking of objects and properties, comparable to words in a language. Just as there can be many distinct words referring to the same object or property, so too there can be distinct concepts that apply to the same property. All the above arguments demonstrate, according to these philosophers, is that we have different ways of conceiving of qualia, and that it isn't obvious that they pick out the same properties. But just as the fact that we had to learn that water is identical to H₂O does not impugn the claim that they are identical, so too the fact that we have to learn that a certain quale is a certain neural property does not refute the claim that they are indeed the very same property.

EXPLANATORY GAP

Proponents of property dualism respond that there are important differences between the water–H₂O case and the case of qualia that undermine the analogy pushed by materialists (Chalmers 1996). However, even if the conceivability and knowledge arguments do not demonstrate that qualia are, as Smart put it, "irreducibly psychical," they do point toward another problem, one that goes under the name of the "explanatory gap" (Levine 1983, 2001). The problem is this. If qualitative sensory experiences are really nothing over and above the interplay of neural firing in the relevant part of the brain, then one would expect that the qualitative character of particular types of sensations could be explained and predicted by reference to their neurophysiological embodiments. Yet, when we consider what it is like to see a red rose or a yellowy-orange after-image, it seems completely arbitrary that it should be the result of this type of neural firing as opposed to some other. In fact, it seems totally arbitrary that it should be like anything at all, merely from a knowledge of the neural properties. In this sense there seems to

be an explanatory gap between the underlying level of neurophysiological phenomena and the level of qualitative experience. Thomas Nagel (1974) makes a similar argument about the limits of materialist understanding by noting that as much as we learn about the echolocation sense of bats, we can never learn thereby what it is like to be a bat and to sense the world in this way.

Faced with these strong intuitions that there is something suspect about the connection between physical properties of the nervous system and qualia, materialists have adopted two different strategies. The first is to attempt to straightforwardly dispel these anti-materialist intuitions by coming up with materialist theories of qualia that are intuitively acceptable. The second is to grant the apparent mystery involved in the connection between qualia and neurophysiological properties, but to argue that there are reasons why this connection should appear so mysterious that do not in the end contradict the basic tenets of materialism.

In line with the first strategy, Smart (1959) himself addressed the problem by proposing what he called a "topic-neutral" analysis of qualitative character. His claim was that our notion of qualitative character is neutral with respect to the kind of material in which it is embodied. Rather, to have a sensation of a yellowy-orange after-image, for instance, is to occupy a state that is similar to the state one is in when actually seeing an orange. This idea was then later developed by functionalists such as H. Putnam (1991), who identified mental states of all kinds with causal roles. That is, a particular mental state is defined as a state that is caused in certain characteristic ways (by physical stimuli and other mental states) and has certain characteristic effects (particular forms of behavior as well as other mental states). On this view the connection between a particular qualitative sensory state and a brain state is truly contingent, since it is allowed that any other physical state that filled the same causal role would count as an instance of this qualitative state.

Adopting functionalism for qualia might seem to provide the materialist with a response both to the conceivability argument and to the problem of the explanatory gap. It is conceivable that a creature might experience a certain sensory quality without being in a particular physical state since there are many different physical states that can support the relevant causal role. Also, one might occupy a certain physical state without having the sensory experience because that state is not connected in the right way to other states, and therefore is not playing the appropriate causal role. As for the explanatory gap, the idea is that appeal to the intrinsic

physical properties of a brain state don't explain its mental, or qualitative character, because qualitative character is a function of the relations that physical state maintains with other internal physical states, as well as stimuli and behavior. The proper locus of explanation for the qualitative character of experience is the overall pattern of interactions among the subject's internal states; it is a matter of the structure, not the "stuff" in which the structure is embodied.

However, it turns out that almost the very same problems that attended the identity theory return to haunt functionalism as well. Take the conceivability argument. In the form of the "inverted qualia" and "absent qualia" hypotheses the conceivability argument can be mounted against functionalism as well. The inverted qualia hypothesis is the conjecture that there could be two functionally identical creatures—that is, both creatures, though made of different material, possess a set of internal states that maintain the very same pattern of interactions with each other and the relevant inputs and outputs to the system—that experience very different qualia when occupying the very same functional state.

The standard illustration of this possibility is known as the "inverted spectrum hypothesis." Oversimplifying greatly for now, consider the fact that the color wheel can be inverted in such a way as to maintain all of the similarity relations. That is, if one creature sees blue and green where another sees yellow and red, and vice versa, then all of their judgments about the relative similarities of objects with respect to color would converge. Imagine that this inversion occurred at birth, so they learned to use color terms the same way. Jack and Jill might both call a ripe tomato red, though Jack's experience is qualitatively like what Jill would experience were she looking at a ripe cucumber.

If such an inversion of qualia with respect to functional roles is possible, then the qualitative character of a sensory experience cannot be identified with its functional role. To make matters worse, it seems perfectly coherent to imagine a creature that satisfies the relevant functional description, and yet for whom there is no conscious experience occurring at all. (Often such creatures are known as "zombies" in the literature.) Ned Block (1980) describes a very compelling example. Imagine, he says, the entire nation of China connected by phone lines in such a way that, collectively, they satisfy the same functional description as a human brain. Would we want to say that the entire nation of China, as a single subject, is seeing red, or feeling pain? Certainly it seems at least possible that no genuine experience is going on at all. Hence

having a qualitative sensation cannot be merely a matter of possessing internal states that play a certain functional, or causal role.

THE DILEMMA

The objections to both the identity theory and functionalism reveal a deep dilemma for materialists about qualia. The qualitative character of a sensation—the way color looks, the way pain feels—strongly seems to be an intrinsic property of the sensation, a matter of how things are with one at that moment, not a matter of how one is disposed to act or what effects are likely. In this sense the identity theory seems quite appropriate, since it identifies the qualitative character of an experience with a physical property of the brain state one occupies at that moment. The problem is that there seems to be no intelligible connection between the physical properties of brain states and the qualitative properties of sensory experiences.

If, however, we pin qualitative character on the pattern of relations that a sensory state maintains with other states, as well as stimuli and behavior, then we can see how appeal to the physical properties of brain states could play an important explanatory role. We can explain how it is that the neural state one occupies when, say, experiencing a yellowy-orange after-image, interacts with other neural states and stimuli and behavior so as to realize the relevant pattern by appeal to the causal mechanisms of the brain and nervous system. The only problem here is that, as demonstrated by the inverted and absent qualia hypotheses, qualitative character is not convincingly characterizable as a matter of the pattern of interactions among internal states. Thus the materialist is faced with this dilemma: Qualitative character is explicable in physical terms only if it can be characterized as a pattern of causal relations among mental states, but only a theory of qualitative character that treats it as an intrinsic property of mental states will be intuitively acceptable.

Functionalism is a structural theory of qualitative character—a particular quale is identified with a particular niche in the overall system of causal interactions among stimuli, internal states, and behavior. Another structural theory worthy of mention is what we might call the "quality space" theory, proposed by Austen Clark in 1993. On this view we start with the idea that different sensory modes—vision, hearing, etc.—define quality spaces. A quality space is a multidimensional space whose axes are determined by the number of independent parameters along which sensory experiences in a given mode can vary. To take again an admittedly oversimplified example, consider color vision. Colors vary along

three dimensions: hue, brightness, and saturation. A particular color (where this means a determinate shade) can then be identified with a vector representing its values in each of the three dimensions. Assuming colors only vary in these three ways (which is part of the oversimplification), then a person's similarity judgments about colors can be predicted and explained by the distances among the relevant color vectors. A complete map of a sensory system can be drawn once all of the independent parameters of variation have been determined. Qualia, then, are points in quality spaces.

The quality space view differs from functionalism in that the structure by reference to which a quale is defined is not a pattern of causal interactions, but rather a quality space. However, it shares with functionalism the idea that it is structural relations rather than intrinsic features of the experience that determine qualitative character. Also, like functionalism, on the quality space view the appeal to the physical features of neural states comes in to explain how the relevant structure is embodied. This allows for the possibility of many alternative physical embodiments for the same quality space, so long as the overall structure of relations among the elements is preserved. Unfortunately, also like functionalism, the quality space view is subject as well to the problems of the inverted and absent qualia hypotheses. So with respect to the general dilemma facing the materialist it does not improve on functionalism.

REPRESENTATIONALISM

A view that seems to promise a way to overcome the materialist's dilemma is "representationalism," discussed in the work of Fred Dretske (1995), G. Harman (1990), William Lycan (1987), and Michael Tye (1995). One way to motivate the theory is to start from an untenable but nevertheless quite tempting theory of qualia and then see representationalism as a way to capture the spirit of the original view while removing its fatal weakness. The tempting but untenable view is this. Qualia, rather than features of mental states, are properties of external objects. They are the colors, sounds, and textures out there in the world that our senses detect. This view is tempting for two reasons. First, it removes qualia as obstacles to a materialist solution to the mind-body problem, since qualia are no longer features of mental states. Second, it is intuitively plausible. Advocates of the view often defend it by citing the so-called transparency of sensory experience. If asked to describe what it is like to have various sensory experiences, one finds oneself describing the properties of external objects. One says

things like "it looks like a lemon," "it tastes like chicken," or "it feels smooth."

The reason the view is untenable is that it cannot handle cases of hallucination or illusion. Suppose one "sees" a pink elephant where there is nothing remotely pink or elephant-like. Clearly one is having a sensory experience with a "pinkish" qualitative character, yet there is no object out there in the world that is pink. Hence the quale cannot be the pink of the elephant, it has to be a feature of one's experience, a property of one's internal mental state. Representationalism comes into play at this point. According to this view, sensory states are mental states that represent the way the world is around us. They differ from belief states in being nonconceptual, more picturelike, but they share with beliefs and thoughts the feature of representing the world. Qualia, then, are the representational contents of sensory experiences. That is, to have a "pinkish" qualitative character is for one's visual state to have the content that something out there in the world is pink. Notice that representationalism shares with the original view the core idea that pinkness is primarily a feature of external objects, but it nevertheless accommodates hallucination and illusion. Just as one can think that there are pink elephants even though there aren't any, so too one can have visual experiences that represent pink elephants even though there aren't any.

While representationalism has many virtues, there are two primary problems. First, the view is less plausible when applied to bodily sensations like pains and itches than when applied to colors and sounds. What does the qualitative character of an itch or a headache represent? Advocates of representationalism maintain that these sensations represent conditions of the body. Whether this view can be sustained is a matter of controversy. The main problem, however, is that representationalism does not overcome the basic challenge facing other materialist theories. Just as functionalism and quality space theory have trouble with inversion and zombie scenarios, so too does representationalism. It seems easy to imagine a creature who normally sees objectively red objects the way others see objectively green objects, and it also seems possible for there to be creatures, or devices, that meet the relevant specifications for representing the qualities of external objects in a "sensory" format but for whom there is nothing it is like to occupy these representational states. Properly programmed computers certainly seem like possible examples. Hence the principal challenge to materialist theories of qualia remains.

PHENOMENAL CONCEPTS

Some materialist philosophers dismiss the inverted and absent qualia hypotheses, along with the conceivability argument, by insisting that the intuitions that underlie these challenges are just that—intuitions—and should not be accorded much significance. Daniel Dennett (1988) and Georges Rey (1997) go so far as to embrace eliminativism, the view that qualia do not really exist. We think we have these features of experience, but in fact they represent a kind of cognitive illusion. However, other materialists, such as Brian Loar (1997), William Lycan (1987), Colin McGinn, David Papineau (2002), Scott Sturgeon (2000), and Michael Tye (1995), insist on the reality of qualia and grant the import of the intuitive resistance to materialism. Their strategy is to attempt to provide a satisfactory materialist theory of the intuitive resistance itself. For many the main tool in this endeavor is the notion of a “phenomenal concept.”

Phenomenal concepts are the special concepts of qualitative properties that we employ when thinking of our qualitative states from within the first-person point of view. When one considers what it is like to see a red rose, and then says something like, “How can *that* be merely a matter of neurons firing in a certain pattern?” one is employing a phenomenal concept to think about the experience. The proposal then is to explain the stubborn cognitive resistance to materialist theories (of whatever form) by appeal to peculiar features of phenomenal concepts. It is a feature of our cognitive architecture, on this view, that we cannot come to see how the qualitative character of our experience is just a matter of the way our neurons are firing. We are doomed to suffer from an explanatory gap, but that we are so doomed is itself explainable in perfectly respectable materialist terms.

Whether this appeal to phenomenal concepts can do the work of extricating materialism from the challenges posed by qualia is still a matter of controversy. It appears that the cluster of problems comprising consciousness, qualia, and subjectivity are destined to haunt the philosophy of mind for some time to come.

QUALITY AND QUANTITY

See *Categories; Dialectical Materialism; Primary and Secondary Qualities*

QUANTIFIERS IN FORMAL LOGIC

Familiarity with classical quantification theory is presupposed here. Some proposed amendments are considered, as are several additions.

ALTERNATIVES TO CLASSICAL QUANTIFICATION THEORY

First-order logic can be reformulated so as to avoid quantifiers and variables. This is only partially done in modal logic, which avoids explicit quantification over possible states of the world in favor of operators \Box and \Diamond . However, in principle all quantification is avoidable, if one is willing to admit enough operators and does not worry about their having ordinary-language readings. In practice, however, few have preferred this predicate-functor approach (see Quine 1960, Benthem 1977). Thus, even such dissidents as the intuitionists adopt the classical quantificational language, though the properties they ascribe to the quantifiers are nonclassical. (Thus, while classically \forall and $\neg\neg\forall$ and $\forall\neg\neg$ are equivalent, intuitionistically the first is stronger than the second and the second stronger than the third.)

Classical logic allows terms formed from constants and function symbols, subject to the restriction that each term must denote some element of the domain over which the quantifiers range; but terms are eliminable using Bertrand Russell's theory of descriptions. On the classical Tarskian definition of truth in a model, truth of $\forall x\phi(x)$ (respectively, $\exists x\phi(x)$) is equivalent to the truth of $\phi(t)$ for all (respectively, some) terms t only in special cases, as when each element of the domain is the denotation of some term of the language (which is never so if the domain is uncountable and the language countable). By contrast, the so-called substitutional quantifier \prod (respectively, Σ) is defined by the condition that $\prod x\phi(x)$ (respectively, $\Sigma x\phi(x)$) always counts as true if and only if

(iff) $\phi(t)$ is true for all (respectively, some) terms t . There is no technical obstacle to introducing such operators, but whether there is any philosophical advantage to doing so is controversial. In particular, if one has in mind a specific domain, \prod (respectively, Σ) will be intuitively equivalent to the ordinary language "for every (respectively, some) element of the domain" only in special cases (see Kripke 1976). Antithetical to substitutional quantification is so-called free logic, which drops the classical restriction that all terms must have denotations and gives up the classical inferences from $\forall x\phi(x)$ to $\phi(t)$ and from $\phi(t)$ to $\forall x\phi(x)$ (see Bencivenga 1983).

EXTENSIONS OF CLASSICAL QUANTIFICATION THEORY

In contrast to the various anticlassical logics just mentioned, by far the largest body of work on quantifiers in formal logic concerns certain extraclassical logics, called model-theoretic logics. These accept classical logic and the Tarskian definition of truth in a model, but introduce additional kinds of quantifiers into the language, indicating their intended meaning by adding clauses for them to the Tarskian definition. There are several kinds (see Barwise and Feferman 1985).

CARDINALITY QUANTIFIERS. Though there are nineteenth-century and even medieval antecedents, the modern theory of such quantifiers as "most" begins with Andrzej Mostowski (1957). Given a formula $\phi(x)$ and a model with domain A , write $\phi[a]$ to indicate that $a \in A$ satisfies $\phi(x)$; also write $\text{card } B$ for the cardinality of a set B . Then the truth conditions for the most studied Mostowski-style quantifiers are as shown in Table 1.

All these generalized quantifiers count as logical notions according to the definition of Alfred Tarski (1986) (which requires that any sentence involving a purportedly logical operator that is true in a model remains true if the model is replaced by an isomorphic one). Their theory has been worked out in some detail. For example, for first-order logic plus Q_0 the Löwenheim-Skolem theorem holds but the compactness theorem fails, while for Q_1 the opposite is the case.

PLURAL QUANTIFIERS. So-called second-order and higher-order quantifiers are nowadays generally read as first-order quantifiers, but with a different domain from that of the first-order quantifiers. Thus, one writes " $\exists X(Xy \ \& \ \dots)$ " but reads it as something like "There is a class X such that y is a member of X and ..." or "There is a concept X such that y falls under X and ..." and simi-

TABLE 1

Quantifier	Truth condition
Most $x\phi(x)$	card $\{a: \phi[a]\} > \text{card } \{a: \neg\phi[a]\}$
More $x[\phi(x), \psi(x)]$	card $\{a: \phi[a]\} > \text{card } \{a: \psi[a]\}$
Q₀ $x\phi(x)$	card $\{a: \phi[a]\}$ infinite
Q₁ $x\phi(x)$	card $\{a: \phi[a]\}$ uncountable
H $x\phi(x)$	card $\{a: \phi[a]\} = \text{card } A$
R $xy\phi(x)$	for some infinite $I \subseteq A$, $\psi[a, b]$ for all distinct $a, b \in I$

larly for the two-place “ $\exists X(Xyz \ \& \ \dots)$ ” and the third-order “ $\exists X(XY \ \& \ \dots)$,” with *relation* and *class of classes* in place of *class*.

George S. Boolos (1984) suggests a different reading, “There are some things, the *x*s, such that *y* is one of them.” Such a reading is available only in the second-order, one-place case, but there it seems to offer a way of avoiding overt quantification over classes or concepts. But it is controversial whether such plural quantification is prior to such notions as that of class, or whether the use of the plural involves a covert “ontological commitment” to something like classes. Boolos argues against the reduction of plural to class quantification, on the grounds that “[t]here are some classes such that any class is one of them iff it is not a member of itself” is true, while “[t]here is a class of classes such that any class” is false.

GAME QUANTIFIERS. Any first-order sentence is equivalent to one in *prenex* form, with all quantifiers out front. Any first-order prenex is equivalent to an existential second-order sentence (quantifying over functions from and to the domain *A* of the first-order variables), called its Skolem form, as with this equivalent pair (where the alternation of quantifiers may go on for any finite number *n* of rounds):

- (1) $\forall x_1 \exists y_1 \forall x_2 \exists y_2 \dots \phi(x_1, y_1, x_2, y_2, \dots)$
- (2) $\exists f_1 \exists f_2 \dots \forall x_1 \forall x_2 \dots \phi(x_1, f(x_1), x_2, f(x_1, x_2), \dots)$

Leon Henkin (1961) observes that one can associate to (1) a game for two players: player A chooses some $a_1 \in A$, player E chooses some $b_1 \in A$, A chooses a_2 , then E chooses b_2, \dots , and in the end E wins if $\phi[a_1, b_1, a_2, b_2, \dots]$, and A if not. A strategy for a player is a rule telling that player how to play on each move as a function of the opponent’s previous moves. A winning strategy is one such that, if the player plays according to it, then the

player will win, regardless of how the opponent plays. A strategy for E can be represented as a pair of functions, one giving E’s first move as a function of A’s first move, the other giving E’s second move as a function of A’s first two moves. Then, (2) asserts that there is a winning strategy for E.

The game interpretation is especially useful if one wants to consider infinitely long formulas. A sentence like (1) but with an infinite alternation of quantifiers can be thought of as describing an infinite game—one may imagine each move made twice as fast as the one before—and the assertion that there exists a winning strategy for E is expressible as an infinitely long second-order sentence like (2) with infinite blocks of existential second-order and universal first-order quantifiers. There is this difference, that for a finite game one or the other of the players must have a winning strategy, but not for infinite games except in special cases. One such special case is that where ϕ is a conjunction of formulas ϕ_1, ϕ_2, \dots , each involving only finitely many of the *x*’s and *y*’s. This game quantifier has a tractable theory in this case (see Moschovakis 1972).

BRANCHING QUANTIFIERS. Henkin (1961) also introduces branching quantifiers and suggests an interpretation in terms of an associated Skolem form, illustrated by the following pair:

- (3) $\forall x_1 \exists y_1 \phi(x_1, y_1, x_2, y_2)$
 $\forall x_2 \exists y_2$
- (4) $\exists f_1 \exists f_2 \phi(x_1, f(x_1), x_2, f_2(x_2))$

Note the subtle difference between (4) and (2): In the latter, f_2 is a one-place function. The main result about Henkin quantifiers is the Enderton-Walkoe theorem, asserting that not only is every Henkin quantifier sentence equivalent to an existential second-order sentence but also the converse holds. This means that known results about the logic of existential second-order sentences immediately apply to the logic of Henkin quantifier sentences: the Löwenheim-Skolem theorem, the compactness theorem, the definability of truth for sentences of this class by a sentence of the class, and more.

Jaako Hintikka (1996) introduces a nonbranching notation, in which (3) would be written as follows:

- (5) $\forall x_1 \exists y_1 \forall x_2 \exists y_2 / x_1 \phi(x_1, y_1, x_2, y_2)$

The “/*x*₁” is read “independent of *x*₁.” Hintikka, long an advocate of a game interpretation of first-order quantifi-

cation, also suggests a game interpretation of the new quantifiers, in terms of a game of imperfect information, in which at the time of E's second move, E has available only information about A's second move, not about A's first move—which is most easily imagined if one thinks of E as a team, with different members making different moves and having available different information when doing so. Hintikka calls the logic with these quantifiers independence-friendly (or information-friendly) logic and makes strong and controversial claims about the philosophical significance of theorems about existential second-order sentences when restated for “IF” logic (see Hintikka 1996; compare Tennant 1998; see also Hodges 1997; Burgess 2003).

Which quantifiers considered by logicians have natural-natural language counterparts, and how close those counterparts are, is a much discussed question that cannot be addressed in this entry.

QUANTITY

See *Measurement and Measurement Theory*

QUANTUM COMPUTING AND TELEPORTATION

In the 1980s and 1990s a series of revolutionary developments in the foundations of quantum mechanics led to what would later become the thriving fields of quantum information, quantum computation, and quantum cryptography. The roots of this revolution lie in the debate between Albert Einstein and Niels Bohr on the interpretation of quantum mechanics, specifically in the notion of “entangled” quantum states at the heart of the Einstein-Podolsky-Rosen argument for the incompleteness of quantum mechanics. What Einstein, Podolsky, and Rosen showed in their 1935 paper “Can Quantum-Mechanical Description of Physical Reality be Considered Complete?” was that composite quantum systems, consisting of spatially separated subsystems, could exist in certain states with peculiar nonclassical correlations between the outcomes of measurements on the subsystems. They argued that these correlations are incompatible with the assumption that the quantum state is a complete description of the system.

In a two-part commentary on the paper, Schrödinger referred to these states as being “entangled.” Roughly

thirty years later John Bell re-examined the Einstein-Podolsky-Rosen argument and showed that quantum mechanics could not be completed in the way Einstein would have liked, because the correlations of entangled states violate an inequality that an Einsteinian completion of quantum mechanics would have to satisfy. Essentially Bell showed that the correlations are inconsistent with any explanation in terms of a common cause (whether deterministic or stochastic) originating in the preparation of the state.

The salient feature of quantum information-processing tasks is the exploitation of entanglement as a new physical resource. Entanglement can be used to teleport quantum states, to exponentially outperform classical computers, and to implement cryptographic procedures that are impossible classically.

TELEPORTATION AS REMOTE “STEERING”

Schroödinger regarded entangled states as problematic because they allow the possibility of what he called remote “steering,” which he regarded as unacceptable in a physical theory. As it turns out the teleportation of quantum states is an experimentally confirmed application of remote “steering” between two separated systems.

Consider Alice and Bob, the traditional protagonists in any two-party communication protocol. Suppose Alice and Bob each holds one of a pair of quantum particles associated with binary-valued physical quantities or “observables.” An example would be a pair of spin-½ particles, with two possible values, + and –, for the spin in some direction, say the z-direction. Alice’s particle might be represented by the pure quantum state $|+\rangle_A$ and Bob’s particle by the pure quantum state $|-\rangle_B$. A spin state is represented as a unit vector in a 2-dimensional vector space, a so-called Hilbert space, the representation space for quantum states. The state of the composite two-particle system is a product state:

$$|+\rangle_A |-\rangle_B$$

represented by a vector in the 4-dimensional product Hilbert space for the two particles. An entangled pure state is a linear sum or “superposition” of product states that cannot itself be expressed as a product state. (More generally, for mixed states, representing mixtures or probability distributions of pure states, an entangled state is a state that cannot be represented as a convex combination or probability distribution of product states.)

Suppose Alice and Bob each holds one of a pair of particles in the entangled state:

$$|\psi\rangle = \frac{1}{\sqrt{2}} (|+\rangle_A |-\rangle_B - |-\rangle_A |+\rangle_B)$$

The coefficients (here $\pm 1/\sqrt{2}$) can be complex numbers in general, and the squares of the absolute values of the coefficients (which are required to sum to 1: here ½ in both cases) represent the probabilities of obtaining the corresponding values of the relevant observables on measurement (+ and –, or – and +, for A and B). It turns out that Bob’s state, which defines the statistics for measurement outcomes on his particle, can be represented as an equal weight mixture of the orthogonal states $|+\rangle_B$, $|-\rangle_B$, but equivalently as an infinity of other mixtures including, to take a specific example, the equal weight mixture of the four nonorthogonal states, represented as superpositions with complex coefficients $\pm\alpha$, $\pm\beta$ in the 2-dimensional Hilbert space of Bob’s particle:

$$|\phi_1\rangle_B = \alpha|+\rangle_B + \beta|-\rangle_B$$

$$|\phi_2\rangle_B = \alpha|+\rangle_B - \beta|-\rangle_B$$

$$|\phi_3\rangle_B = \beta|+\rangle_B + \alpha|-\rangle_B$$

$$|\phi_4\rangle_B = \beta|+\rangle_B - \alpha|-\rangle_B$$

If Alice measures the spin observable with outcomes associated with the two possible states $|+\rangle_A$, $|-\rangle_A$ on her particle A, and Bob measures the corresponding spin observable on his particle B, Alice’s outcomes will be oppositely correlated with Bob’s outcomes (+ with –, and – with +). If instead Alice prepares a spin-½ particle A’ in the state $|\phi\rangle_{A'} = \alpha|+\rangle_{A'} + \beta|-\rangle_{A'}$ and measures an observable on the pair of systems A+A’ in her possession with possible outcomes corresponding to the four orthogonal states:

$$|1\rangle = \frac{1}{\sqrt{2}} (|+\rangle_{A'} |-\rangle_A - |-\rangle_{A'} |+\rangle_A)$$

$$|2\rangle = \frac{1}{\sqrt{2}} (|+\rangle_{A'} |-\rangle_A + |-\rangle_{A'} |+\rangle_A)$$

$$|3\rangle = \frac{1}{\sqrt{2}} (|+\rangle_{A'} |+\rangle_A - |-\rangle_{A'} |-\rangle_A)$$

$$|4\rangle = \frac{1}{\sqrt{2}} (|+\rangle_{A'} |+\rangle_A + |-\rangle_{A'} |-\rangle_A)$$

(the so-called Bell states), she will obtain the outcomes 1, 2, 3, 4 with equal probability, and these outcomes will be correlated with Bob’s states $|\phi_1\rangle_B$, $|\phi_2\rangle_B$, $|\phi_3\rangle_B$, $|\phi_4\rangle_B$ (i.e., if

Bob checks to see whether his particle is in the state $|\phi_i\rangle_B$ when Alice reports that she obtained the outcome $i=1, 2, 3, 4$, he will find that this is always in fact the case). This follows because:

$$|\phi_1\rangle_{A'}|\psi\rangle = \frac{1}{2}(-|1\rangle|\phi_1\rangle_B - |2\rangle|\phi_2\rangle_B + |3\rangle|\phi_3\rangle_B + |4\rangle|\phi_4\rangle_B)$$

In this sense, Alice can “steer” Bob’s particle into any equivalent mixture generating the same statistics by an appropriate local measurement.

Now, remote “steering” in this probabilistic sense is precisely what makes quantum teleportation possible. Suppose Alice and Bob share a pair of spin- $\frac{1}{2}$ particles A and B in the entangled state and Alice is given a spin- $\frac{1}{2}$ particle A' in an *unknown* state $|\phi_1\rangle$. There is no procedure by which Alice can determine the unknown state, but if Alice measures the composite system $A+A'$ in the Bell basis, she will “steer” Bob’s particle into one of the states $|\phi_1\rangle_B, |\phi_2\rangle_B, |\phi_3\rangle_B, |\phi_4\rangle_B$ with equal probability. If Alice tells Bob the outcome of her measurement, Bob can apply a local operation corresponding to a transformation in the Hilbert space of his particle to obtain the state $|\phi_1\rangle_B$.

Note that before Alice sends Bob the outcome of her measurement, the quantum state that Bob assigns to his particle—the information represented by the mixed state—is unchanged by Alice’s measurement operation, even though after Alice’s measurement the probability is $\frac{1}{4}$ that the state of Bob’s particle is in fact $|\phi_1\rangle$ (in this case the local operation to obtain the state is represented by the identity). The trick that results in the transference of the state $|\phi_1\rangle$ from Alice to Bob, without the particle A' traveling from Alice to Bob, is the ability afforded Alice by the shared entangled state to correlate one of four measurement outcomes (each occurring with probability $\frac{1}{4}$) with one of four states that together represent a particular decomposition of Bob’s mixed state. The transference of the state of A' to Bob’s particle is accomplished by Bob’s operation, which requires that Alice sends the information about her measurement outcome to Bob. In the teleportation protocol the state of the particle A' is destroyed by Alice’s measurement and recreated as the state of Bob’s particle by Bob’s operation—in fact, the systems A and A' end up in an entangled state as the result of Alice’s measurement. (Note that if the state $|\phi_1\rangle$ of A' were not destroyed there would be two copies of the state, which would violate the quantum “no cloning” theorem.)

COMPUTATION VIA ENTANGLEMENT

The field of quantum computation was launched in the 1980s with two seminal papers by David Deutsch in 1985 and Richard Feynman in 1982. The basic idea can be

illustrated by the first genuinely quantum algorithm, proposed by Deutsch, later improved by Duetsch and Jozsa in 1992.

Consider a function f that maps an input value $x=0$ or $x=1$ onto an output value that is either 0 or 1. The algorithm for computing f might be quite complicated. To take Mermin’s example, $f(x)$ might represent the value of the millionth bit in the binary expansion of $\sqrt{2+x}$, so that $f(0)$ is the millionth bit in the expansion of $\sqrt{2}$ while $f(1)$ is the millionth bit in the expansion of $\sqrt{3}$. Suppose we are interested in whether the function $f(x)$ is constant for both values of x or takes different values for both values of x —whether the millionth bit of $\sqrt{2}$ is the same as the millionth bit of $\sqrt{3}$, or not. With a classical computer we would have to run through the algorithm twice to evaluate $f(0)$ and $f(1)$ and then compare these values. With a quantum computer it is possible to answer the question in a single run of the algorithm.

We might represent the computation of f by a classical computer as follows:

$$\begin{aligned} \langle 0 \rangle \langle 0 \rangle &\rightarrow \langle 0 \rangle \langle f(0) \rangle \\ \langle 1 \rangle \langle 0 \rangle &\rightarrow \langle 1 \rangle \langle f(1) \rangle \end{aligned}$$

where $\langle x \rangle \langle f(x) \rangle$ represents the input and output registers for the computation, and \rightarrow represents the mapping defined by the algorithm.

In the case of a quantum computer the input and output registers are quantum states, specifically here “qubits,” or states represented as orthogonal vectors in a 2-dimensional Hilbert space:

$$\begin{aligned} |0\rangle|0\rangle &\rightarrow |0\rangle|f(0)\rangle \\ |1\rangle|0\rangle &\rightarrow |1\rangle|f(1)\rangle \end{aligned}$$

Here \rightarrow represents the quantum mechanical implementation of the algorithm by quantum transformations of the input state. We could put the input register into a superposition of quantum states $\frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$, in which case, since the quantum transformations are linear maps, the quantum implementation of the algorithm yields:

$$\frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)|0\rangle \rightarrow \frac{1}{\sqrt{2}}(|0\rangle|f(0)\rangle + |1\rangle|f(1)\rangle)$$

This state is a linear superposition of *both* possible inputs and the associated outputs of f , apparently representing the computation for *all* possible values. Unfortunately however only a single read-out is possible: if we make a measurement on both registers, we obtain just one of the possible results with probability $\frac{1}{2}$, and the original state,

in which all possible inputs and associated outputs are represented, is altered. So there is no advantage over a classical computer.

Now we are interested in a global property of f , whether f is constant or balanced. Remarkably it turns out that we can answer this question in just one run of the algorithm, but at the expense of foregoing any information about the value of the function for either input. The final state is a product state (of the two registers) if $f(0) = f(1)$ and an entangled state if $f(0) \neq f(1)$. By appropriate quantum transformations (see the discussion in Mermin's *Lecture Notes on Quantum Computation*) this state can be transformed to:

$$|1\rangle(|f(0)\rangle - |\overline{f(0)}\rangle)$$

if $f(0) = f(1)$, and to:

$$|0\rangle(|f(0)\rangle - |\overline{f(0)}\rangle)$$

if $f(0) \neq f(1)$, where $\overline{0} = 1$ and $\overline{1} = 0$. The outcome of a measurement on the input register, + or -, will distinguish whether $f(0) = f(1)$ or $f(0) \neq f(1)$.

Note that a measurement of the output register will yield the value $f(0)$ or $\overline{f(0)}$ with probability $\frac{1}{2}$, that is, 0 or 1 with probability $\frac{1}{2}$, which provides no information about the value of f for either input. In general a quantum computation involves the evolution of correlations in successive entangled states to a final state in which a measurement can determine the answer to a question about a global property of a function. The global property here is a disjunctive property:

$$(f(0) = f(1) = 0) \vee (f(0) = f(1) = 1)$$

or:

$$((f(0) = 1) \wedge (f(1) = 0)) \vee ((f(0) = 0) \wedge (f(1) = 1))$$

and the computation yields one or other of these disjunctions in the final measurement, which excludes the possibility of recording of the values of the disjuncts. The two alternative disjunctions are represented in the 4-dimensional Hilbert space of the two registers as quantum disjunctions, corresponding to two orthogonal 2-dimensional planes. Depending on whether the function is constant or balanced, the final state of the two registers is represented by a vector lying in one or the other of these two planes, and this can be determined by a measurement of the input register.

The Deutsch-Jozsa algorithm is a simple example of a quantum algorithm. More sophisticated quantum computation algorithms, such as Shor's algorithm for finding

the prime factors of a number, demonstrate an exponential speed-up over classical computation. The foundational significance of quantum computation concerns our understanding of computational complexity, that is, the relative efficiency of computational algorithms, rather than our characterization of the class of computable functions as those functions computable by a Turing machine. What quantum computation achieves is the possibility of solving a problem in a run-time (or number of computational steps) that increases as a polynomial function of the size of the input, while the computation using a classical computer would require superpolynomial, typically exponential, time. The difference can be quite dramatic. A classical computer of the sort available as of this writing would take an amount of time longer than the age of the universe to factor a 250-digit number into its two prime factors, using the fastest known algorithm. By contrast a quantum computer using Shor's algorithm could find the factors in minutes.

QUANTUM LOGIC AND PROBABILITY

Quantum physics predicts many astonishing physical effects that have been subsequently observed in the laboratory. Perhaps the most significant effect is the violation of Bell's inequality, which implies a failure of classical locality. But the most widely known bit of quantum magic is the experiment of Clinton Davisson and Lester Germer demonstrating interference effects for electrons. Richard Feynman said this is a phenomenon "which is impossible, *absolutely* impossible, to explain in any classical way, and which has in it the heart of quantum mechanics. In reality, it contains the *only* mystery" (1963–1965, Vol. 3, p. 1-1). As we will see, Feynman somewhat overstates the case, but let us first try to get in his frame of mind.

The interference effect is illustrated by the two-slit experiment. If we send a plain water wave toward a barrier with two narrow slits in it, we find that a circular wave is produced on the far side of each slit. As these two circular waves expand, they eventually overlap and interfere. Where the crest of one meets the crest of the other, we get a crest of twice the height; where the trough of one meets the trough of the other, we get a trough of twice the depth; and where the crest of one meets the trough of the other, the waves cancel out. This creates *interference bands*: regions of extreme agitation where the waves meet in phase, crest-to-crest and trough-to-trough, juxtaposed with quiescent regions where the waves meet out of phase, crest-to-trough. The pattern of regions of high and low activity is easy to calculate. Notice, in particular, that there are places where one would observe wave motion if either slit alone were open, but where there are no waves when both slits are open, because of destructive interference.

In quantum theory, a *wave function* represents the physical state of an electron, and for a *single* electron the wave function is mathematically similar to a water wave. (It is not exactly the same, since it is a *complex-valued* function. Moreover, this analogy works only for a *single* electron. The wave function for a pair of electrons is defined on the configuration space of the system, which has more dimensions than physical space.) The dynamics of the wave function is similar enough to the dynamics of water waves to display the same interference effects. That is, in the case of a single electron shot at a screen with a single slit, the wave function that makes it through the slit spreads out on the far side in a sort of circular pattern. And in the case of a single electron shot at a screen with two slits, the wave function that gets through spreads out in two circular patterns, one centered at each slit, and these interfere where they overlap, just like the water waves.

Of course, when we actually *look for* a single electron, we never find it spread out; we always find it at some localized place. We can use the wave function to make predictions about where the electron will appear by squaring the wave function and interpreting this value as the *probability* that the particle will be found at a particular location. If we do many identically prepared experiments, we find that the distribution of the electrons matches the square of the amplitude of the wave function, thereby confirming the predictive accuracy of quantum mechanics. But the mystery is this: To get these interference effects, we do not have to send many electrons *at the same time*. We can send the electrons through the device one at a time, with long gaps between them, and watch the interference bands build up slowly, dot by dot. So it is not that different electrons are somehow interfering *with each other*; it is rather that each electron is somehow interfering *with itself*.

To make the effect even more vivid, consider this fact. We send electrons through the slits one at a time and watch for flashes on a distant screen. There are particular areas on the distant screen where we will sometimes see flashes when only the right slit is open, and sometimes see flashes when only the left slit is open, but *never* see flashes (because of destructive interference) when both slits are open. So each electron sent through when both slits are open must somehow be physically influenced by the fact that both are open, since that region is only forbidden when both are open. But, to put the question fancifully, how can an electron "know" that both slits are open if (being a tiny particle) it only goes through one slit?

This would appear to be a straightforward *physical* question that calls for a *physical* answer. And indeed, two different physical answers are available, corresponding to the two straightforward ways to interpret the quantum formalism. On the one hand, if one thinks that the wave function is *complete*, that is, that it encodes all the physical characteristics of the electron, then one will simply reject that claim that the electron is a tiny particle that can only go through one slit. If the wave function is complete, then when the wave function spreads out enough to go through both slits, the electron itself spreads out enough to go through both slits, and that is how it can interfere with itself. This leaves a mystery, but the mystery is not why there is interference. Rather, it is why the electron makes a small, localized flash on the far screen. This problem is solved, in this approach, by giving an account of wave-function collapse.

The second physical answer maintains that the electron is indeed a tiny particle that always has a well-defined location, and hence goes through one slit or the other. On this approach, the wave function is *not* complete, since it does not indicate what that position is. This account is realized in the “pilot wave” theory of Louis de Broglie and David Bohm. As John Bell has written, “While the founding fathers agonized over the question: ‘particle’ or ‘wave’, de Broglie in 1925 proposed the obvious answer: ‘particle’ and ‘wave.’” That is, in the view of de Broglie and Bohm, there is, in addition to the located particle, a wave function that *guides the trajectory* of the particle. The state of the wave function is influenced by the fact that both slits are open, in exactly the way the quantum formalism indicates. So each particle “knows” that both slits are open, even though it goes through only one, because the *wave function* “knows” that both slits are open, and the wave function guides the particle.

These two physical answers to the puzzle of the interference bands are perfectly adequate, and evidently require no adjustments to classical logic or probability theory. The solution of de Broglie and Bohm is even, in certain sense, a classical solution, contrary to Feynman’s worry. So there is nothing in the phenomena discovered by modern physics that could *require* us to abandon or modify classical logic or probability theory.

Nonetheless, there have been many attempts, of various sorts, to argue that a change in logic or probability theory is at least *suggested* by the mathematical form of quantum theory, or that a change in logic or probability will produce an interpretation that is both physically adequate and somehow preferable to the two physical solutions outlined above.

At this point one would like a clear account of how classical logic or probability theory might be changed, and how the change might help us understand phenomena like the two-slit experiment without recourse to the sorts of physical hypotheses discussed above (hypotheses that, by the way, are already used to solve the measurement problem in quantum theory). Unfortunately, no such clear account is possible, because despite a long history and many attempts, no such account has ever been produced. So in its place, we must search instead for the reasons that anyone ever thought that classical logic or probability theory is responsible for the “mystery” surrounding these phenomena.

There are several different routes that can lead us to call into question classical logic. One, followed by Feynman in his famous *Lectures on Physics* (1963–1965), proceeds by reasoning about the two-slit experiment. The other, which is the foundation of the technical field of quantum logic, proceeds from an analysis of the mathematical machinery of quantum theory. Let us examine these in turn.

In his analysis of the two-slit experiment, Feynman first introduced proposition A:

Proposition A. Each electron *either* goes through slit 1 *or* goes through slit 2.

Feynman then went on to consider what he calls the *consequences* of this proposition for predictions about the results of the experiment. If proposition A is true, he said, then we ought to be able to calculate the probability that the electron will land at any point of the screen by first determining the probability for electrons that go through slit 1 (by blocking slit 2 and seeing what happens), and then determining the probability for electrons that pass through slit 2 (by blocking slit 1 and seeing what happens). If proposition A is true when both slits are open, Feynman said, then the individual probabilities derived from these experiments should add. With both slits open, there are more ways for any result to come about (since an electron can get to a certain spot either by going through slit 1 or by going through slit 2), and the chance of the result should be just the sum of the chances of each process. This is, of course, not what we see. Because of the interference, there are places on the far screen where electrons appear with either slit open, but where no electrons appear with both slits open. Feynman concluded, “When one does *not* try to tell which way the electron goes, when there is nothing in the experiment to disturb the electrons, then one may *not* say that an electron goes through either hole 1 or hole 2. If one does say that, and starts to make deductions from the statement, he will make errors

in the analysis.” That is, Feynman concludes from considerations of how the probabilities ought to add that proposition A is not true.

We can equally well present Feynman’s dilemma using only logic rather than probability theory. There are places on the screen where an electron can appear when only slit 1 is open (and the electron goes through slit 1) and also when only slit 2 is open (and the electron goes through slit 2). So if the electron goes through slit 1, it can appear at a certain point, and if it goes through slit 2, it can appear at that same point. From the premise that the electron either goes through slit 1 or goes through slit 2, it then follows by a disjunctive syllogism that it can appear at that point. But with *both* slits open, the electron cannot appear at that point. It seems to follow that when both slits are open, the disjunction is not true. It is not the case that the electron went through slit 1 or went through slit 2.

Something must have gone wrong with Feynman’s analysis somewhere. For in the theory of de Broglie and Bohm, electrons always have exact locations, and every electron that gets from the source to the far screen goes either through slit 1 or through slit 2. And the de Broglie and Bohm theory makes all the right predictions: exactly the predictions of quantum theory. Where did Feynman go wrong?

The solution is not hard to seek. Feynman considers first doing an experiment with slit 1 open *and* slit 2 closed, and then an experiment with slit 2 open *and* slit 1 closed. So the experimentally confirmed propositions are that if the electron goes through slit 1 with slit 2 closed, it can appear at a certain spot, and that if it goes through slit 2 with slit 1 closed, it can appear at that spot. The relevant disjunction for using disjunctive syllogism is the following: The particle either goes through slit 1 with slit 2 closed or through slit 2 with slit 1 closed. From this disjunction it does indeed follow that the electron can appear at the spot. But this disjunction tells us nothing at all about what can happen *with both slits open*.

Feynman’s thought, evidently, is that if the electron goes through one slit, then it cannot make any difference whether the other slit is open. This is a reasonable conjecture, supported by classical intuitions. But this conjecture is false, and quantum theory shows why it is false: The state of the wave function is influenced by the state of both slits. Indeed, one consequence of quantum mechanics is that the state of the wave function is influenced by the presence or absence of detectors at either slit. Even when both slits are open, a detector at one slit will cause the interference to go away *even when the detector does not*

fire. This is a straightforward mathematical consequence of the dynamics of the wave function. The ultimate *physical* moral is that one must take account of the entire experimental arrangement when considering what quantum mechanics predicts. As John Bell put it, “When one forgets the role of the apparatus . . . , one despairs of ordinary logic. . . . Hence ‘quantum logic.’ When one remembers the role of the apparatus, ordinary logic is just fine.” And the apparatus in question is the *whole experimental situation*, including elements (such as the presence or absence of detectors that *do not fire*) that would be deemed irrelevant in classical physics.

Feynman’s argument is a *physical* argument: It proceeds solely from the observation of experimental results to the (incorrect) conclusion that proposition A cannot be true, since one could deduce a false consequence from it. The field of quantum logic takes the opposite tack. Quantum logicians want to maintain that something like proposition A is *true* when both slits are open. But since false claims can apparently be deduced from proposition A using classical logic, this requires a change in logic itself.

Quantum logicians tend not to start from experiment, as Feynman does, but from observations about the form of the mathematical apparatus used in quantum theory. In particular, they begin with the observation that the space of all wave functions is a complex *vector space*. This means that given any pair of wave functions $|\psi_1\rangle$ and $|\psi_2\rangle$, and any two complex numbers α and β , there exists another wave function of the form $\alpha|\psi_1\rangle + \beta|\psi_2\rangle$. Such a wave function is called a *superposition* of $|\psi_1\rangle$ and $|\psi_2\rangle$.

Suppose that the wave function of an electron that goes through slit 1 with slit 2 closed is $|\psi_1\rangle$, and the wave function of an electron that goes through slit 2 with slit 1 closed is $|\psi_2\rangle$. Then when *both* slits are open, the wave function will be of the form $\alpha|\psi_1\rangle + \beta|\psi_2\rangle$, a superposition of $|\psi_1\rangle$ and $|\psi_2\rangle$. (In particular, in the usual experimental configuration, it will be $(1/\sqrt{2})|\psi_1\rangle + (1/\sqrt{2})|\psi_2\rangle$.) This wave function is evidently neither $|\psi_1\rangle$ nor $|\psi_2\rangle$. It would *not* be correct to say, with classical logical connectives, that the electron is either in state $|\psi_1\rangle$ or in state $|\psi_2\rangle$. So if we allow $|\psi_1\rangle$ now to stand for the *proposition* that the electron is in state $|\psi_1\rangle$, and $|\psi_2\rangle$ to stand for the proposition that the electron is in state $|\psi_2\rangle$, then the classical proposition “ $|\psi_1\rangle$ or $|\psi_2\rangle$ ” is *false* when both slits are open.

What the quantum logician does, though, is to introduce a *new* connective, usually written \vee , that is defined so that $|\psi_1\rangle \vee |\psi_2\rangle$ is true whenever the electron is in a superposition of $|\psi_1\rangle$ and $|\psi_2\rangle$. If one tries to think of \vee as

a sort of disjunction, one can then have a disjunction that is true even though neither disjunct is true—a circumstance that violates classical truth conditions.

More technically, the quantum logician associates propositions with subspaces of Hilbert space, the vector space of the wave function. The “conjunction” of two propositions (written $\mathbf{A} \wedge \mathbf{B}$) is just the *intersection* of the associated subspaces, and the “disjunction” of two propositions ($\mathbf{A} \vee \mathbf{B}$) is the *span* of the subspaces, that is, the subspace consisting of all vectors that can be formed by adding vectors from the two given subspaces. A proposition is *true* just in case the wave function of the system lies in the associated subspace. So if the wave function of the system is $(1/\sqrt{2})|\psi_1\rangle + (1/\sqrt{2})|\psi_2\rangle$, then the proposition $|\psi_1\rangle$ is not true, and the proposition $|\psi_2\rangle$ is not true, but the proposition $|\psi_1\rangle \vee |\psi_2\rangle$ is true.

With this terminology in place, one can easily show that the set of “quantum propositions” form a non-Boolean (nondistributive) lattice under the operations \vee and \wedge . This is a straightforward mathematical fact about the structure of subspaces of Hilbert space under these operations. There is no nonclassical logic or probability theory here, just standard mathematics.

Of course, if one starts to pronounce \vee “or” and \wedge “and,” then matters can get somewhat confusing. Because the lattice of quantum propositions is nondistributive, $(\mathbf{A} \vee \mathbf{B}) \wedge \mathbf{C}$ can be true while $(\mathbf{A} \wedge \mathbf{C}) \vee (\mathbf{B} \wedge \mathbf{C})$ is false. If one presents this fact by saying that “(A or B) and C” is true while “(A and C) or (B and C)” is false, then it appears that de Morgan’s laws have failed. Hence the supposed need for quantum logic.

If quantum logic is just the study of the structure of subspaces of Hilbert space, then it is a perfectly legitimate, but badly named, enterprise. It is not an alternative to, or replacement for, classical logic, since it studies connectives that are not the classical connectives. Nothing has been shown to be wrong or misleading about classical logic. Rather, the problem lies with our intuitions about experimental conditions, which lead us incorrectly to expect that whether the second slit is open is irrelevant to the behavior of the electron at the other slit. Quantum mechanics shows not that there is anything wrong with classical logic, but rather that the physics of the quantum world is very unlike the physics of Isaac Newton and James Clerk Maxwell. The surprising relevance of experimental conditions is shown by experiments like the two-slit experiment, and the appropriate way to reason about these experiments is, of course, classically.

What about Feynman’s proposition A? With both slits open, is it correct or incorrect to say that the electron either went through slit 1 or slit 2? The answer to this question once again depends on physics rather than logic. If the de Broglie and Bohm theory is correct, then the electron always goes through one slit or the other. Retrospectively, one can even tell which slit it went through. Proposition A is therefore true. If one adopts an interpretation according to which the wave function is complete, then the wave function is all there is to the electron, and the wave function “goes through” both slits. Part of it goes through each slit, so it goes neither *entirely* through slit 1 nor *entirely* through slit 2. On a truth-functional reading of “or,” proposition A is false. As long one is clear about the exact content of any proposition and about the interpretation of quantum theory at issue, classical logic and probability theory work just fine.

QUANTUM MECHANICS

Quantum mechanics has the distinction of being considered both the most empirically successful and the most poorly understood theory in the history of physics.

To take an oft-cited example of the first point: The theoretically calculated value of the anomalous magnetic moment of the electron using quantum electrodynamics matches the observed value to twelve decimal places, arguably the best confirmed empirical prediction ever made. To illustrate the second point, we have the equally oft-cited remarks of Niels Bohr, “Anyone who says that they can contemplate quantum mechanics without becoming dizzy has not understood the concept in the least,” and of Richard Feynman, “[We] have always had (secret, secret, close the doors!) we always have had a great deal of difficulty in understanding the world view that quantum mechanics represents.” How could both of these circumstances obtain?

For the purposes of making predictions, quantum theory consists in a mathematical apparatus and has clear enough rules of thumb about how to apply the mathematical apparatus in various experimental situations. If one is doing an experiment or observing something, one must first associate a mathematical *quantum state* or *wave function* with the system under observation. For example, if one prepares in the laboratory an electron beam with a fixed momentum, then the quantum state of each electron in the beam will be something like a sine wave. In the case of a single particle it is common to visualize this wave function as one would a water wave: as an object extended in space. Although this visualization works for a single particle, it does not work in general, so care must be taken. But for the moment, this simple visualization works. The wave function for the electron is “spread out” in space.

The second part of the mathematical apparatus is a *dynamical equation* that specifies how the quantum state changes with time so long as no observation or measurement is made on the system. These equations have names like the *Schrödinger equation* (for nonrelativistic quantum mechanics) and the *Dirac equation* (for relativistic quantum field theory). In the case of the electron mentioned earlier the dynamical equation is relevantly similar to the dynamical equation for water waves, so we can visualize the quantum state as a little plane water wave moving in a certain direction. If the electron is shot at a screen with two slits in it, then the quantum state will behave similarly to a water wave that hits such a barrier: circularly expanding waves will emerge from each slit,

and there will be constructive and destructive interference where those waves overlap. If beyond the slits there is a fluorescent screen, we can easily calculate what the quantum state “at the screen” will look like: It will have the peaks and troughs characteristic of interfering water waves.

Finally comes the interaction with the screen. Here is where things get tricky. One would naively expect that the correct way to understand what happens when the electron wave function reaches the screen is to build a physical model of the screen and apply quantum mechanics to it. But that is not what is done. Instead, the screen is treated as a measuring device and the interaction with the screen as a measurement, and new rules are brought into play.

The new rules require that one first decide what property the measuring device measures. In the case of a fixed screen it is taken that the screen measures the *position* of a particle. If instead of a fixed screen we had an absorber on springs, whose recoil is recorded, then the device would measure the *momentum* of the particle. These determinations are typically made by relying on classical judgments: There is no algorithm for determining what a generic (physically specified) object “measures,” or indeed whether it measures anything at all. But laboratory apparatus for measuring position and momentum have been familiar from before the advent of quantum theory, so this poses no real practical problem.

Next, the property measured gets associated with a mathematical object called a *Hermitian operator*. Again, there is no algorithm for this, but for familiar classical properties like position and momentum the association is established. For each Hermitian operator there is an associated set of wave functions called the *eigenstates* of the operator. It is purely a matter of mathematics to determine the eigenstates. Each eigenstate has associated with it an *eigenvalue*: The eigenvalues are supposed to correspond to the possible outcomes of a measurement of the associated property, such as the possible values of position, momentum, or energy. (Conversely, it is typically assumed that for every Hermitian operator, there corresponds a measurable property and possible laboratory operations that would measure it, although there is no general method for specifying these.)

The last step in the recipe for making predictions can now be taken. When a system is measured, the wave function for the system is first expressed as a sum of terms, each term being an eigenstate of the relevant Hermitian operator. Any wave function can be expressed as a sum of such terms, with each term given a weight, which is a

complex number. For example, if an operator has only two eigenstates, call them $|1\rangle$ and $|2\rangle$, then any wave function can be expressed in the form $\alpha|1\rangle + \beta|2\rangle$, with α and β complex numbers such that $|\alpha|^2 + |\beta|^2 = 1$. (This is the case, for example, when we measure the so-called spin of an electron in a given direction, and always get one of two results: spin up or spin down.) Recall that each eigenstate is associated with a possible outcome of the measurement: $|1\rangle$, for example, could be associated with getting spin up, and $|2\rangle$ with getting spin down. The quantum mechanical prediction is now typically a probabilistic one: the chance of getting the result associated with $|1\rangle$ is $|\alpha|^2$, and the chance of getting the result associated with $|2\rangle$ is $|\beta|^2$. In general, one writes out the wave function of the system in terms of the appropriate eigenstates, and then the chance of getting the result associated with some eigenstate is just the square of the complex number that weights the state.

We can now see how quantum theory makes empirical predictions: So long as one knows the initial quantum state of the system and the right Hermitian operator to associate with the measurement, the theory will allow one to make probabilistic predictions for the outcome. Those predictions turn out to be exquisitely accurate.

If a Hermitian operator has only a finite number of eigenstates, or the eigenvalues of the operator are discrete, then any associated measurement should have only a discrete set of possible outcomes. This has already been in the case of spin; for a spin-1/2 particle such as an electron, there are only two eigenstates for the spin in a given direction. Physically, this means that when we do an experiment to measure spin (which may involve shooting a particle through an inhomogeneous magnetic field) we will get only one of two results: Either the particle will be deflected up a given amount or down a given amount (hence spin up and spin down). In this case the physical quantity is *quantized*; it takes only a discrete set of values. But quantum theory does not require all physical magnitudes to be quantized in this way; the position, momentum, or energy of a free particle is not. So the heart of quantum theory is not a theory of discreteness, it is rather just the mathematical apparatus and the rules of application described earlier.

THE MEASUREMENT PROBLEM

Why, then, is the quantum theory so puzzling, or so much more obscure than, say, classical mechanics? One way that it differs from classical theory is that it provides only probabilistic predictions for experiments, and one might well wonder, as Albert Einstein famously did, whether

this is because “God plays dice with the universe” (i.e., the physical world itself is not deterministic) or whether the probabilities merely reflect our incomplete knowledge of physical situation. But even apart from the probabilities, the formulation of the theory is rather peculiar. Rules are given for representing the physical state of a system and for how that physical state evolves and interacts with other systems when no measurement takes place. This evolution is perfectly deterministic. A different set of rules is applied to derive predictions for the outcomes of experiments, and these rules are not deterministic. Still, an experiment in a laboratory is just a species of physical interaction, and ought to be treatable as such. There should be a way to describe the physical situation in the lab, and the interaction of the measured system with the measuring device, that relies only on applying, say, the Schrödinger equation to the physical state of the system plus the lab.

John S. Bell put this point succinctly, “If you make axioms, rather than definitions and theorems, about the ‘measurement’ of anything else, then you commit redundancy and risk inconsistency” (1987, p. 166). You commit redundancy because while the axioms about measurement specify what should happen in a measurement situation, the measurement situation, considered as a simple physical interaction, ought also to be covered by the general theory of such interactions. You risk inconsistency because the redundancy produces the possibility that the measurement axioms will contradict the results of the second sort of treatment. This is indeed what happens in the standard approaches to quantum mechanics. The result is called the *measurement problem*.

The measurement problem arises from a conflict in the standard approach between treating a laboratory operation as a normal physical interaction and treating it as a measurement. To display this conflict, we need some way to represent the laboratory apparatus as a physical device and the interaction between the device and the system as a physical interaction. Now this might seem to be a daunting task; a piece of laboratory apparatus is typically large and complicated, comprising astronomically large numbers of atoms. By contrast, exact wave functions are hard to come by for anything much more complicated than a single hydrogen atom. How can we hope to treat the laboratory operation at a fundamental level?

Fortunately, there is a way around this problem. Although we cannot write down, in detail, the physical state of a large piece of apparatus, there are conditions that we must assume if we are to regard the apparatus as a good measuring device. There are necessary conditions

for being a good measuring device, and since we do regard certain apparatus as such devices, we must be assuming that they meet these conditions.

Take the case of spin. If we choose a direction in space, call it the x -direction, then there is a Hermitian operator that gets associated with the quantity x -spin. That operator has two eigenstates, which we can represent as $|x\text{-up}\rangle_s$ and $|x\text{-down}\rangle_s$. The subscript s indicates that these are states of the system to be measured. We have pieces of laboratory equipment that can be regarded as good devices for measuring the x -spin of a particle. We can prepare such an apparatus in a state, call it the “ready” state, in which it will function as a good measuring device. Again, we do not know the exact physical details of this ready state, but we must assume such states exist and can be prepared. What physical characteristics must such a ready state have?

Besides the ready state, the apparatus must have two distinct indicator states, one of which corresponds to getting an “up” result of the measurement and the other that corresponds to getting a “down” result. And the key point about the physics of the apparatus is this: It must be that if the device in its ready state interacts with a particle in the state $|x\text{-up}\rangle_s$, it will evolve into the indicator state that is associated with the up result, and if it interacts with a particle in state $|x\text{-down}\rangle_s$, it will evolve into the other indicator state.

This can be put in a formal notation. The ready state of the apparatus can be represented by $|\text{ready}\rangle_A$, the up indicator state by $|\text{“up”}\rangle_A$, and the down indicator state by $|\text{“down”}\rangle_A$. If we feed an x -spin up particle into the device, the initial physical state of the system plus apparatus is represented by $|x\text{-up}\rangle_s|\text{ready}\rangle_A$, if we feed in an x -spin down particle the initial state is $|x\text{-down}\rangle_s|\text{ready}\rangle_A$. If the apparatus is, in fact, a good x -spin measuring device, then the first initial state must evolve into a state in which the apparatus indicates up, that is, it must evolve into $|x\text{-up}\rangle_s|\text{“up”}\rangle_A$, and the second initial state must evolve into a state that indicates down, that is, $|x\text{-down}\rangle_s|\text{“down”}\rangle_A$. Using an arrow to represent the relevant time evolution, then, we have for any good x -spin measuring device

$$|x\text{-up}\rangle_s|\text{ready}\rangle_A \rightarrow |x\text{-up}\rangle_s|\text{“up”}\rangle_A \text{ and}$$

$$|x\text{-down}\rangle_s|\text{ready}\rangle_A \rightarrow |x\text{-down}\rangle_s|\text{“down”}\rangle_A.$$

We have not done any real physics yet, we have just indicated how the physics must come out if there are to be items that count as good x -spin measuring devices, as we think there are.

The important part of the physics that generates the measurement problem is the arrow in the representations listed earlier, the physical evolution that takes one from the initial state of the system plus apparatus to the final state. Quantum theory provides laws of evolution for quantum states such as the Schrödinger and Dirac equations. These would be the equations one would use to model the evolution of the system plus apparatus as a normal physical evolution. And all these dynamical equations have a common mathematical feature; they are all linear equations. It is this feature of the quantum theory that generates the measurement problem, so we should pause over the notion of linearity.

The set of wave functions used in quantum theory form a *vector space*. This means that one can take a weighted sum of any set of wave functions and get another wave function. (The weights in this case are complex numbers, hence it is a complex vector space.) This property was mentioned earlier when it was noted that any wave function can be expressed as a weighted sum of the eigenvectors of an observable. An operator on a vector space is just an object that maps a vector as input to another vector as output. If the operator O maps the vector \mathbf{A} to the vector \mathbf{B} , we can write that as

$$O(\mathbf{A}) = \mathbf{B}.$$

A linear operator has the feature that you get the same result whether to operate on a sum of two vectors or you first operate on the vectors and then takes the sum. That is, if O is a linear operator, then for all vectors \mathbf{A} and \mathbf{B} ,

$$O(\mathbf{A} + \mathbf{B}) = O(\mathbf{A}) + O(\mathbf{B}).$$

The dynamical equations evidently correspond to operators; they take as input the initial physical state and give as output the final state, after a specified period has elapsed. But further, the Schrödinger and Dirac equations correspond to linear operators. Why is this important?

We have already seen how the physical state of a good x -spin measuring device must evolve when fed a particle in the state $|x\text{-up}\rangle_s$ or the state $|x\text{-down}\rangle_s$. But these are not the only spin states that the incoming particle can occupy. There is an infinitude of spin states, which correspond to all the wave functions that can be expressed as $\alpha|x\text{-up}\rangle_s + \beta|x\text{-down}\rangle_s$, with α and β complex numbers such that $|\alpha|^2 + |\beta|^2 = 1$. Correspondingly, there is an infinitude of possible directions in space in which one can orient a spin measuring device, and each of the directions is associated with a different Hermitian operator. For a direction at right angles to the x -direction, call it the y -direction, there are eigenstates $|y\text{-up}\rangle_s$ and

$|y\text{-down}\rangle_s$. These states can be expressed as weighted sums of the x -spin eigenstates, and in the usual notation

$$|y\text{-up}\rangle_s = 1/\sqrt{2}|x\text{-up}\rangle_s + 1/\sqrt{2}|x\text{-down}\rangle_s \text{ and}$$

$$|y\text{-down}\rangle_s = 1/\sqrt{2}|x\text{-up}\rangle_s - 1/\sqrt{2}|x\text{-down}\rangle_s.$$

So what happens if we feed a particle in the state $|y\text{-up}\rangle_s$ into the good x -spin measuring device?

Empirically, we know what happens: About half the time the apparatus ends up indicating “up” and about half the time it ends up indicating “down.” There is nothing we are able to do to control the outcome: y -up eigenstate particles that are identically prepared nonetheless yield different outcomes in this experiment.

If we use the usual predictive apparatus, we also get this result. The “up” result from the apparatus is associated with the eigenstate $|x\text{-up}\rangle_s$ and the “down” result associated with $|x\text{-down}\rangle_s$. The general recipe tells us to express the incoming particle in terms of these eigenstates as $1/\sqrt{2}|x\text{-up}\rangle_s + 1/\sqrt{2}|x\text{-down}\rangle_s$, and then to take the squares of the weighting factors to get the probabilities of the results. This yields a probabilistic prediction of 50 percent chance “up” and 50 percent chance “down,” which corresponds to what we see in the lab.

But if instead of the usual predictive apparatus we use the general account of physical interactions, we get into trouble. In that case, we would represent the initial state of the system plus apparatus as $|y\text{-up}\rangle_s|ready\rangle_A$. The dynamical equation can now be used to determine the physical state of the system plus apparatus at the end of the experiment.

But the linearity of the dynamical equations already determines what the answer must be. For

$$|y\text{-up}\rangle_s|ready\rangle_A = (1/\sqrt{2}|x\text{-up}\rangle_s + 1/\sqrt{2}|x\text{-down}\rangle_s)|ready\rangle_A$$

$$= 1/\sqrt{2}|x\text{-up}\rangle_s|ready\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|ready\rangle_A.$$

But we know how each of the two terms of this superposition must evolve, since the apparatus is a good x -spin measuring device. By linearity, this initial state must evolve into the final state

$$1/\sqrt{2}|x\text{-up}\rangle_s|“up”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“down”\rangle_A.$$

That is, the final state of the apparatus plus system must be a superposition of a state in which the apparatus yields the result “up” and a state in which the apparatus yields the result “down.” That is what treating the measurement as a normal physical interaction must imply.

So by making axioms about measurements, we have both committed redundancy and achieved inconsistency. The axioms say that the outcome of the experiment is not determined by the initial state; each of two outcomes is possible, with a 50 percent chance of each. But the treatment of the measurement as a normal physical interaction implies that only one final physical state can occur. And furthermore, that final physical state is an extremely difficult one to understand. It appears to be neither a state in which the measuring apparatus is indicating “up” nor a state in which the apparatus is indicating “down,” but some sort of symmetric combination of the two. If all the physical facts about the apparatus are somehow represented in its wave function, then it seems that at the end of the experiment the apparatus can neither be indicating up (and not down) nor down (and not up). But we always see one or the other when we do this experiment.

At this point our attention must clearly be turned to the mathematical object we have called the wave function. The wave function is supposed to represent the physical state of a system. The question is whether the wave function represents all of the physical features of a system, or whether systems represented by the same wave function could nevertheless be physically different. If one asserts the former, then one believes that the wave function is complete, if the latter, then the wave function is incomplete. The standard interpretations of the quantum formalism take the wave function to be complete, interpretations that take it to be incomplete are commonly called *hidden variables* theories (although that is a misleading name).

The wave function $1/\sqrt{2}|x\text{-up}\rangle_s|“up”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“down”\rangle_A$ does not represent the apparatus as indicating up (and not down) or as indicating down (and not up). So if the wave function is complete, the apparatus, at the end of the experiment, must neither be indicating up (and not down) nor down (and not up). But that flatly contradicts our direct experience of such apparatus. This is the measurement problem. As Bell puts it, “Either the wave function, as given by the Schrödinger equation, is not everything, or it is not right” (1987, p. 201).

COLLAPSE INTERPRETATIONS

COLLAPSE TIED TO OBSERVATION. What is one to do? From the beginning of discussions of these matters, Einstein held the argument to show that the wave function is not everything and hence that quantum mechanics is incomplete. The wave function might represent part of the physical state of a system, or the wave function might

represent some features of ensembles, collections, or systems, but the wave function cannot be a complete representation of the physical state of an individual system, like the particular x -spin measuring device in the laboratory after a particular experiment is done. For after the experiment, the apparatus evidently either indicates “up” or it indicates “down,” but the wave function does not represent it as doing so.

By contrast, the founders of the quantum theory, especially Bohr, insisted that the wave function is complete. And they did not want to deny that the measuring device ends up indicating one determinate outcome. So the only option left was to deny that the wave function, as given by the Schrödinger equation, is right. At some times, the wave function must evolve in a way that is not correctly described by the Schrödinger equation. The wave function must “collapse.” The standard interpretation of quantum mechanics holds that the wave function evolves, at different times, in either of two different ways. This view was given its canonical formulation in John von Neumann’s *Mathematical Foundations of Quantum Mechanics* (1955). Von Neumann believed (incorrectly, as we will see) that he had proven the impossibility of supplementing the wave function with hidden variables, so he thought the wave function must be complete. When he comes to discuss the time evolution of systems, Von Neumann says “[w]e therefore have two fundamentally different types of interventions which can occur in a system S First, the arbitrary [i.e., nondeterministic] changes by measurement. ... Second, the automatic [i.e., deterministic] changes which occur with the passage of time” (p. 351). The second type of change is described by, for example, the Schrödinger equation, and the first by an indeterministic process of collapse.

What the collapse dynamics must be can be read off from the results we want together with the thesis that the wave function is complete. For example, in the x -spin measurement of the y -spin up electron, we want there to be a 50 percent chance that the apparatus indicates “up” and a 50 percent chance that it indicates “down.” But the only wave function that represents an apparatus indicating “up” is $|\text{“up”}\rangle_A$, and the only wave function for an apparatus indicating “down” is $|\text{“down”}\rangle_A$. So instead of a deterministic transition to the final state

$$1/\sqrt{2}|x\text{-up}\rangle_S|\text{“up”}\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_S|\text{“down”}\rangle_A$$

we must postulate an indeterministic transition with a 50 percent chance of yielding $|x\text{-up}\rangle_S|\text{“up”}\rangle_A$ and a 50 percent chance of yielding $|x\text{-down}\rangle_S|\text{“down”}\rangle_A$.

It is clear what the collapse dynamics must do. What is completely unclear, though, is when it must do it. All Von Neumann’s rules say is that we get collapses when measurements occur and deterministic evolutions “with the passage of time.” But surely measurements also involve the passage of time; so under exactly what conditions do each of the evolutions obtain? Collapse theories, which postulate two distinct and incompatible forms of evolution of the wave function, require some account of when each type of evolution occurs.

Historically, this line of inquiry was influenced by the association of the problem with “measurement” or “observation.” If one begins with the thought that the non-linear evolution happens only when a measurement or observation occurs, then the problem becomes one of specifying when a measurement or observation occurs. And this in turn suggests that we need a characterization of an observer who makes the observation. Pushing even further, one can arrive at the notion that observations require a conscious observer of a certain kind, folding the problem of consciousness into the mix. As Bell asks, “What exactly qualifies some physical systems to play the role of ‘measurer’? Was the wave function of the world waiting to jump for thousands of millions of years until a single-celled living creature appeared? Or did it have to wait a little longer, for some better qualified system ... with a Ph.D.?” (1987, p. 117).

This line of thought was discussed by Eugene Wigner, “This way out of the difficulty amounts to the postulate that the equations of motion of quantum mechanics cease to be linear, in fact that they are grossly non-linear if conscious beings enter the picture” (1967, p. 183). Wigner suggests that the quantum measurement problem indicates “the effect of consciousness on physical phenomena,” a possibility of almost incomprehensible implications (not the least of which: How could conscious beings evolve if there were no collapses, since the universe would surely be in a superposition of states with and without conscious beings!). In any case, Wigner’s speculations never amounted to a physical theory, nor could they unless a physical characterization of a conscious system was forthcoming.

So if one adopts a collapse theory, and if the collapses are tied to measurements or observations, then one is left with the problem of giving a physical characterization of an observation or a measurement. Such physicists as Einstein and Bell were incredulous of the notion that conscious systems play such a central role in the physics of the universe.

SPONTANEOUS COLLAPSE THEORIES. Nonetheless, precise theories of collapse do exist. The key to resolving the foregoing puzzle is to notice that although collapses must be of the right form to make the physical interactions called “observations” and “measurements” have determinate outcomes, there is no reason that the collapse dynamics itself need mention observation or measurement. The collapse dynamics merely must be of such a kind as to give outcomes in the right situations.

The most widely discussed theory of wave function collapse was developed by Gian Carlo Ghirardi, Alberto Rimini, and Tullio Weber (1986) and is called the spontaneous localization theory or, more commonly, the GRW theory. The theory postulates an account of wave function collapse that makes no mention of observation, measurement, consciousness, or anything of the sort. Rather, it supplies a universal rule for both how and when the collapse occurs. The “how” of the collapse involves localization in space; when the collapse occurs, one takes a single particle and multiplies its wave function, expressed as a function of space, by a narrow Gaussian (bell curve). This has the effect of localizing the particle near the center of the Gaussian, in the sense that most of the wave function will be near the center. If the wave function before the collapse is widely spread out over space, after the collapse it is much more heavily weighted to a particular region. The likelihood that a collapse will occur centered at a particular location depends on the square amplitude of the precollapse wave function for that location. The collapses, unlike Schrödinger evolution, are fundamentally nondeterministic, chancy events.

The GRW collapse does not perfectly locate the wave function at a point. It could not do so for straightforward physical reasons: The localization process will violate the conservation of energy, and the more narrowly the post-collapse wave function is confined, the more new energy is pumped into the system. If there were perfect localizations, the energy increase would be infinite—and immediately evident. (It follows from these same observations that even in the “standard” theory there are never collapses to perfectly precise positions—even after a so-called position measurement.)

Therefore, the GRW theory faces a decision: Exactly how localized should the localized wave function be? This corresponds to choosing a width for the Gaussian: The narrower the width, the more energy that is added to the system on collapse. The choice for this width is bounded in one direction by observation—the energy increase for the universe must be below observed bounds, and particular processes, such as spontaneous ionization, should be

rare—and in the other direction by the demand that the localization solve the measurement problem. As it happens, Ghirardi, Rimini, and Weber chose a value of about 10^{-5} centimeters for the width of the Gaussian. This is a new constant of nature.

Beside the “how” of the collapse, the GRW theory must specify the “when.” It was here that we saw issues such as consciousness getting into the discussion: If collapses occur only when measurements or observations occur, then we must know when measurements or observations occur. The GRW theory slices through this problematic neatly; it simply postulates that the collapses take place at random, with a fixed probability per unit time. This introduces another new fundamental constant: the average time between collapses per particle. The value of that constant is also limited in two directions; on the one hand, we know from interference experiments that isolated individual particles almost never suffer collapses on the time scale of laboratory operations. On the other hand, the collapses must be frequent enough to resolve the measurement problem. The GRW theory employs a value of 10^{15} seconds, or about 100 million years, for this constant.

Clearly, the constant has been chosen large enough to solve one problem: Individual isolated particles will almost never suffer collapses in the laboratory. It is less clear, though, how it solves the measurement problem.

The key here is to note that actual experiments record their outcomes in the correlated positions of many, many particles. In our spin experiment we said that our spin measuring device must have two distinct indicator states: |“up”> and |“down”>. To be a useful measuring device, these indicator states must be macroscopically distinguishable. This is achieved with macroscopic objects—pointers, drops of ink, and so on—to indicate the outcome. And a macroscopic object will have on the order of 10^{23} particles.

So suppose the outcome |“up”> corresponds to a pointer pointing to the right and the outcome |“down”> corresponds to the pointer pointing to the left. If there are no collapses, the device will end up with the wave function $1/\sqrt{2}|x\text{-up}\rangle_s|“up”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“down”\rangle_A$. Now although it is unlikely that any particular particle in the pointer will suffer a collapse on the time scale of the experiment, because there are so many particles in the pointer, it is overwhelmingly likely that some particle or other in the pointer will suffer a collapse quickly: within about 10^{-8} seconds. And (this is the key), since in the state $1/\sqrt{2}|x\text{-up}\rangle_s|“up”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“down”\rangle_A$ all the particle positions are correlated with one another, if the

collapse localizes a single particle in the pointer, it localizes all of them. So, if having the wave functions of all the particles in the pointer highly concentrated on the right (or on the left) suffices to solve the measurement problem, the problem will be solved before 10^{-4} seconds has elapsed.

The original GRW theory has been subject to much discussion. In a technical direction there have been similar theories, by Ghirardi and Rimini and by Philip Pearle, that make the collapses to be continuous rather than discrete. More fundamentally, there have been two foundational questions: First, does the only approximate nature of the “localization” vitiate its usefulness in solving the measurement problem, and second, does the theory require a physical ontology distinct from the wave function? Several suggestions for such an additional ontology have been put forward, including a mass density in space-time, and discrete events (“flashes”) in space-time.

The addition of such extra ontology, beyond the wave function, reminds us of the second horn of Bell’s dilemma: Either the wave function as given by the Schrödinger equation is not right or it is not everything. The versions of the GRW theory that admit a mass density or the flashes postulate that the wave function is not everything, do so in such a way that the exact state of the extra ontology can be recovered from the wave function. The more radical proposal is that there is extra ontology, and its state cannot be read off the wave function. These are the so-called hidden variables theories.

ADDITIONAL VARIABLES THEORIES

According to an additional variables theory, the complete quantum state of the system after a measurement is indeed $1/\sqrt{2}|x\text{-up}\rangle_S|“\text{up}”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_S|“\text{down}”\rangle_A$. The outcome of the measurement cannot be read off of that state because the outcome is realized in the state of the additional variables, not in the wave function. It immediately follows that for any such theory, the additional ontology, the additional variables, had best not be “hidden”: since the actual outcome is manifest, the additional variables had best be manifest. Indeed, on this approach the role of the wave function in the theory is to determine the evolution of the additional variables. The wave function, since it is made manifest only through this influence, is really the more “hidden” part of the ontology.

The best known and most intensively developed additional variables theory goes back to Louis de Broglie, but is most intimately associated with David Bohm. In its nonrelativistic particle version, Bohmian mechanics,

physical objects are constituted of always-located point particles, just as was conceived in classical mechanics. At any given time, the physical state of a system comprises both the exact positions of the particles and a wave function. The wave function never collapses: it always obeys a linear dynamical equation like the Schrödinger equation. Nonetheless, at the end of the experiment the particles in the pointer will end up either all on the right or all on the left, thus solving the measurement problem. This is a consequence of the dynamics of the particles as determined by the wave function.

It happens that the particle dynamics in Bohmian mechanics is completely deterministic, although that is not fundamentally important to the theory and indeterministic versions of Bohm’s approach have been developed. The dynamical equation used in Bohmian mechanics is much more importantly the simplest equation that one can write down if one assumes that the particle trajectories are to be determined by the wave function and that various symmetries are to be respected. If one starts with idea that there are particles and that quantum theory should be a theory of the motion of those particles that reproduces the predictions of the standard mathematical recipe, Bohmian mechanics is the most direct outcome.

Since Bohmian mechanics is a deterministic theory, the outcome of any experiment is fixed by the initial state of the system. The probabilities derived from the standard mathematical recipe must therefore be interpreted purely epistemically: they reflect our lack of knowledge of the initial state. This lack of knowledge turns out to have a physical explanation in Bohmian mechanics: Once one models any interaction designed to acquire information about a system as a physical interaction between a system and an observer, it can be shown to follow that initial uncertainty about the state of the target system cannot be reduced below a certain bound, given by the Heisenberg uncertainty relations.

This illustrates the degree to which the ontological “morals” of quantum theory are held hostage to interpretations. In the standard interpretation, when the wave function of a particle is spread out, there is no further fact about exactly where the particle is. (Because of this, position measurements in the standard theory are not really measurements, i.e., they do not reveal preexisting facts about positions.) In Bohm’s interpretation, when the wave function is spread out, there is a fact about exactly where the particle is, but it follows from physical analysis that one cannot find out more exactly where it is without thereby altering the wave function (more properly, with-

out altering the effective wave function that we use to make predictions). Similarly, in the standard interpretation, when we do a position measurement on a spread out particle, there is an indeterministic collapse that localizes the particle—it gives it an approximate location. According to Bohm’s theory the same interaction really is a measurement: It reveals the location that the particle already had. So it is a fool’s errand to ask after “the ontological implications of quantum theory”: the account of the physical world one gets depends critically on the interpretation of the formalism.

Bohm’s approach has been adapted to other choices for the additional variables. In particular, interpretations of field theory have been pursued in two different ways: with field variables that evolve indeterministically, and with the addition to Bohmian mechanics the possibility of creating and annihilating particles in an indeterministic way. Each of these provides the wherewithal to treat standard field theory.

There have been extensive examinations of other ways to add additional variables to a noncollapse interpretation, largely under the rubric of *modal interpretations*. Both rules for specifying what the additional variables are and rules for the dynamics of the new variables have been investigated.

A THIRD WAY?

There are also some rather radical attempts to reject each of Bell’s two options and to maintain both that the wave function, as given by the Schrödinger equation, is right and that it is everything—that is, it is descriptively complete. Since a wave function such as $1/\sqrt{2}|x\text{-up}\rangle_s|“\text{up}”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“\text{down}”\rangle_A$ does not indicate that one outcome rather than the other occurred, this requires maintaining that it is not the case that one outcome rather than the other occurred.

This denial can come in two flavors. One is to maintain that neither outcome occurred, or even seemed to occur, and one is only somehow under the illusion that one did. David Z. Albert (1992) investigated this option under the rubric the *bare theory*. Ultimately, the bare theory is insupportable, since any coherent account must at least allow that the quantum mechanical predictions appear to be correct.

The more famous attempt in this direction contends that, in some sense, both outcomes occur, albeit in different “worlds.” Evidently, the wave function $1/\sqrt{2}|x\text{-up}\rangle_s|“\text{up}”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“\text{down}”\rangle_A$ can be written as the mathematical sum of two pieces, one of

which corresponds to a situation with the apparatus indicating “up” and the other to a situation with the apparatus indicating “down.” The *many worlds theory* attempts to interpret this as a single physical state, which somehow contains or supports two separate “worlds,” one with each outcome.

The many worlds interpretation confronts several technical and interpretive hurdles. The first technical hurdle arises because any wave function can be written as the sum of other wave functions in an infinitude of ways. For example, consider the apparatus state $1/\sqrt{2}|“\text{up}”\rangle_A + 1/\sqrt{2}|“\text{down}”\rangle_A$. Intuitively, this state does not represent the apparatus as having fired one way or another. This state can be called $|D_1\rangle_A$. Similarly, $|D_2\rangle_A$ can represent the state $1/\sqrt{2}|“\text{up}”\rangle_A - 1/\sqrt{2}|“\text{down}”\rangle_A$, which also does not correspond to an apparatus with a definite outcome. The state $1/\sqrt{2}|x\text{-up}\rangle_s|“\text{up}”\rangle_A + 1/\sqrt{2}|x\text{-down}\rangle_s|“\text{down}”\rangle_A$, which seems to consist in two “worlds,” one with each outcome, can be written just as well as $1/\sqrt{2}|y\text{-up}\rangle_s|D_1\rangle_A + 1/\sqrt{2}|y\text{-down}\rangle_s|D_2\rangle_A$. Written in this way, the state seems to comprise two worlds: one in which the electron has y -spin up and the apparatus is not in a definite indicator state, the other in which the electron has y -spin down, and the apparatus is in a distinct physical state that is equally not a definite indicator state. If these are the “two worlds,” then the measurement problem has not been solved, it has been merely traded as a single world without a definite outcome for a pair of worlds neither of which has a definite outcome.

So the many worlds theory would first have to maintain that there is a preferred way to decompose the global wave function into “worlds.” This is known as the *preferred basis problem*.

A more fundamental difficulty arises when one tries to understand the status of the probabilities in the many worlds theory. In a collapse theory the probabilities are probabilities for collapses to occur one way rather than another, and there is a physical fact about how the collapses occur, and therefore about frequencies of outcomes. In an additional variables theory the probabilities are about which values the additional variables take, and there is a physical fact about the values they take and therefore about frequencies of outcomes. But in the many worlds theory, whenever one does an experiment like the spin measurement described earlier, the world splits: There is no frequency with which one outcome occurs as opposed to the other. And more critically, that the world “splits” has nothing to do with the amplitude assigned to the two daughter worlds.

Suppose, for example, that instead of feeding a y -spin up electron into our x -spin measuring device, we feed in an electron whose state is $1/2|x\text{-up}\rangle_s + \sqrt{3}/2|x\text{-down}\rangle_s$. By linearity, at the end of the experiment, the state of the system plus apparatus is $1/2|x\text{-up}\rangle_s|“up”\rangle_A + \sqrt{3}/2|x\text{-down}\rangle_s|“down”\rangle_A$. Even if we have solved the preferred basis problem and can assert that there are now two worlds, one with each outcome, notice that we are evidently in exactly the same situation as in the original experiment: Whenever we do the experiment, the universe “splits.” But the quantum formalism counsels us to have different expectations in the two cases: in the first case, we should expect to get an “up” outcome 50 percent of the time, in the second case only 25 percent of the time. It is unclear, in the many worlds theory, what the expectations are for, and why they should be different.

Another interpretation of the quantum formalism that has been considered is the *many minds theory* of Barry Loewer and Albert. Despite the name, the many minds theory is not allied in spirit with the many worlds theory: It is rather an additional variables theory in which the additional variables are purely mental subjective states. This is somewhat akin to Wigner’s appeal to consciousness to solve the measurement problem, but where Wigner’s minds affect the development of the wave function, the minds in this theory (as is typical for additional variables theories) do not. The physical measurement apparatus in the problematic case does not end up in a definite indicator state, but a mind is so constituted that it will, in this situation, have the subjective experience of seeing a particular indicator state. Which mental state the mind evolves into is indeterministic. The preferred basis problem is addressed by stipulating that there is an objectively preferred basis of physical states that are associated with distinct mental states.

The difference between the many worlds and the many minds approaches is made most vivid by noting that the latter theory does not need more than one mind to solve the measurement problem, where the problem is now understood as explaining the determinate nature of our experience. A multiplicity of minds are added to Loewer and Albert’s theory only to recover a weak form of mind-body supervenience: Although the experiential state of an individual mind does not supervene on the physical state of the body with which it is associated, if one associates every body with an infinitude of minds, the distribution of their mental states can supervene on the physical state of the body.

A final attempt to address the problems of quantum mechanics deserves brief mention. Some maintain that

the reason quantum mechanics is so confusing is not because the mathematical apparatus requires emendation (e.g., by explicitly adding a collapse or additional variables) or an interpretation (i.e., an account of exactly which mathematical objects represent physical facts), but because we reason about the quantum world in the wrong way. Classical logic, it is said, is what is leading us astray. We merely need to replace our patterns of inference with quantum logic.

There is a perfectly good mathematical subject that sometimes goes by the name *quantum logic*, which is the study, for example, of relations between subspaces of Hilbert space. These studies, like all mathematics, employ classical logic. There is, however, no sense in which these studies, by themselves, afford a solution to the measurement problem or explain how it is that experiments like those described earlier have unique, determinate outcomes.

THE WAVE FUNCTION, ENTANGLEMENT, EPR, AND NON-LOCALITY

For the purposes of this discussion, the wave function has been treated as if it were something like the electromagnetic field: a field defined on space. Although this is not too misleading when discussing a single particle, it is entirely inadequate when considering collections of particles. The wave function for N particles is a function not on physical space, but on the $3N$ -dimensional configuration space, each point of which specifies the exact location of all the N particles. This allows for the existence of entangled wave functions, in which the physical characteristics of even widely separated particles cannot be specified independently of one another.

Consider R and L , a pair of widely separated particles. Among the wave functions available for this pair is one that ascribes x -spin up to R and x -spin down to L , which is written as $|x\text{-up}\rangle_R|x\text{-down}\rangle_L$, and one that attributes x -spin down to R and x -spin up to L : $|x\text{-down}\rangle_R|x\text{-up}\rangle_L$. These are called *product states*, and all predictions from these states about how R will respond to a measurement are independent of what happens to L , and vice versa.

But besides these product states, there are entangled states like the *singlet state*: $1/\sqrt{2}|x\text{-up}\rangle_R|x\text{-down}\rangle_L - 1/\sqrt{2}|x\text{-down}\rangle_R|x\text{-up}\rangle_L$. In this state the x -spins of the two particles are said to be anticorrelated since a measurement of their x -spins will yield either up for R and down for L or down for R and up for L (with a 50 percent chance for each outcome). Even so, if the wave function is complete, then neither particle in the singlet state has a

determinate x -spin: the state is evidently symmetrical between spin up and spin down for each particle considered individually.

How can the x -spins of the particles be anticorrelated if neither particle has an x -spin? The standard answer must appeal to dispositions: although in the singlet state neither particle is disposed to display a particular x -spin on measurement, the pair is jointly disposed to display opposite x -spins if both are measured. Put another way, on the standard interpretation, before either particle is measured neither has a determinate x -spin, but after one of them is measured, and, say, displays x -spin up, the other acquires a surefire disposition to display x -spin down. And this change occurs simultaneously, even if the particles happen to be millions of miles apart.

Einstein found this to be a fundamentally objectionable feature of the standard interpretation of the wave function. In a paper coauthored with Boris Podolsky and Nathan Rosen (EPR 1935), Einstein pointed out this mysterious, instantaneous “spooky action-at-a-distance” built into the standard approach to quantum theory. It is uncontroversial that an x -spin measurement carried out on L with, say, an “up” outcome” will result in a change of the wave function assigned to R: It will now be assigned the state $|x\text{-down}\rangle_R$. If the wave function is complete, then this must reflect a physical change in the state of R because of the measurement carried out on L, even though there is no physical process that connects the two particles. What EPR pointed out (using particle positions rather than spin, but to the same effect) was that the correlations could easily be explained without postulating any such action-at-a-distance. The natural suggestion is that when we assign a particular pair of particles the state $1/\sqrt{2}|x\text{-up}\rangle_R|x\text{-down}\rangle_L - 1/\sqrt{2}|x\text{-down}\rangle_R|x\text{-up}\rangle_L$, it is a consequence of our ignorance of the real physical state of the pair: The pair is either in the product state $|x\text{-up}\rangle_R|x\text{-down}\rangle_L$ or in the product state $|x\text{-down}\rangle_R|x\text{-up}\rangle_L$, with a 50 percent chance of each. This simple expedient will predict the same perfect anticorrelations without any need to invoke a real physical change of one particle consequent to the measurement of the other.

So matters stood until 1964, when Bell published his famous theorem. Bell showed that Einstein’s approach could not possibly recover the full range of quantum mechanical predictions. That is, no theory can make the same predictions as quantum mechanics if it postulates (1) that distant particles, such as R and L, have each their own physical state definable independently of the other and (2) measurements made on each of the particles have

no physical affect on the other. Entanglement of states turns out to be an essential feature—arguably the central feature—of quantum mechanics. And entanglement between widely separated particles implies non-locality: The physics of either particle cannot be specified without reference to the state and career of the other.

The spooky action-at-a-distance that Einstein noted is not just an artifact of an interpretation of the quantum formalism; it is an inherent feature of physical phenomena that can be verified in the laboratory. A fundamental problem is that the physical connection between the particles is not just spooky (unmediated by a continuous space-time process), it is superluminal. It remains unclear to this day how to reconcile this with the theory of relativity.

QUINE, WILLARD VAN ORMAN

(1908–2000)

Willard Van Orman Quine, an Edgar Pierce professor of philosophy at Harvard, was born in Akron, Ohio. In 1930 he was graduated from Oberlin, where he majored in mathematics, and he wrote a doctoral dissertation in logic under Alfred North Whitehead at Harvard. He visited Vienna, studied mathematical logic at Warsaw, and at Prague met Rudolf Carnap, whose work was to inspire and influence him.

Some of Quine's publications are in philosophy, some in symbolic logic, and others are concerned with the logical regimentation of ordinary language. It is his philosophy and related aspects of his advocated regimentation of language that concern us here, his contributions to logic being dealt with elsewhere.

ANALYTIC-SYNTHETIC DISTINCTION

Some philosophers have attempted to distinguish between such statements as "A river flows through Brisbane," which, they contend, are true as a matter of fact, and statements like "No bachelor is married," the truth of which is said to be independent of matters of fact. The former have been described as synthetic, the latter as analytic. Quine maintained, first, that the analytic-synthetic distinction has never satisfactorily been made and, second, that there is no good reason for believing that it can be made.

LOGICAL TRUTH. Given a list of logical particles and the notion of truth, with which Quine was comparatively satisfied, we may, he contends, derive the notion of logical truth. "All birds are birds" is logically true because it is both true and such that if we leave its logical parts alone and replace "birds" with some other word, then if we get a statement at all, we get a true one—for example, "All snakes are snakes." But even though this analytic statement is logically true, there are analytic statements like "No bachelor is married" that are not, and thus analyticity remains to be explained. If we replace "bachelor" with the synonymous "unmarried man," we have a logical truth, and it would thus appear that an analytic statement either is a logical truth or is reducible to one by interchange of synonyms.

SYNONYMY. However, according to Quine, an account of analyticity that depends on the notion of synonymy is unsatisfactory. Suppose that all and only Guards officers

are very tall soldiers with long hair. Since "Guards officers" and "very tall soldiers with long hair" are coextensive expressions, there are statements whose truth or falsity cannot be affected by interchanging these expressions. But because they are not synonymous expressions, there are also statements like "Necessarily, all and only Guards officers are Guards officers" that can be so affected. In contrast, the truth of the statement "Necessarily, all and only bachelors are bachelors" cannot be affected by interchanging "bachelors" and "unmarried men" because these expressions are synonymous. But to make the last statement is to say that "All and only bachelors are bachelors" is analytic. Thus, we give an account of synonymy in terms of the effects of interchanging expressions in certain contexts. But because these contexts cannot be specified without reference to analyticity or some equivalent notion, we cannot, without circularity, use the notion of synonymy in giving an account of analyticity. Similar difficulties frustrate the derivation of self-contradictoriness from logical falsity.

Quine also discusses the possibility of giving an account of the analyticity of statements in artificial languages, but here, as in natural languages, the difficulty is, he contended, that each of the key notions in the theory of meaning is definable only in terms of the others.

Anyone who produced an account of these notions acceptable to Quine would thereby refute him, but what sort of account this would be remains to be seen. In the meantime the strongest argument against him is *ad hominem*. "All the illuminated manuscripts are illuminated" is logically true only if "illuminated" has the same meaning in each of its occurrences. Thus, the notion of logical truth, which Quine accepts, is dependent upon the notion of synonymy, which he rejects.

RADICAL TRANSLATIONS. Quine's theory of meaning was further developed in his discussion of the difficulties that would arise if we were to attempt to translate the language of a hitherto isolated tribe. Radical translation, as he calls it, would have to begin not with words but with those sentences that have a comparatively direct relation to stimulus conditions. The stimulus meaning of a sentence for a person is defined in terms of the class that has as its members the kinds of stimulation that would prompt the person's assent to the sentence. Intrasubjective stimulus synonymy is sameness of stimulus meaning for one speaker, and two sentences are socially stimulus-synonymous if they are intrasubjectively stimulus-synonymous for nearly everyone who speaks the language. A sentence is stimulus-analytic for a person if he would

assent to it, if to anything, after every stimulation, and a socially stimulus-analytic sentence is stimulus-analytic for nearly every speaker of the language.

In order to see that these are not our intuitive notions of synonymy and analyticity, we need to distinguish occasion sentences and standing sentences. If every minute or so we are asked to assent to “John has hiccups,” we cannot do so without having another look at John on each occasion. In contrast, having once assented to the standing sentence “Salt is soluble in water,” we may assent again without observing salt or anything else again. Applied to occasion sentences, intrasubjective stimulus synonymy approximates sameness of meaning; standing sentences, however, are related to experience indirectly, and the kinds of stimulus that would prompt assent to a standing sentence vary from speaker to speaker. Thus, the stimulus meaning of a standing sentence falls short of our intuitive notion of meaning; stimulus synonymy is correspondingly inadequate, and some socially stimulus-analytic sentences would normally be described not as analytic but as conveying information common to the whole community.

Quine demands of those who talk of analyticity and synonymy that they give of their concepts the sort of account in terms of dispositions to verbal behavior that he has given of his.

By observing and testing native speech behavior dispositions, the linguist can come to translate some occasion sentences and to recognize stimulus analyticity and synonymy. But in order to complete the radical translation of a language, he must frame analytical hypotheses. This consists of segmenting what he hears into native words and hypothetically equating these to English expressions. Quine contends that there will be many sets of analytical hypotheses that fit all native dispositions to speech behavior and yet lead to incompatible translations of countless sentences in their language. Suppose that, observing the circumstances in which a native utters “Gavagai,” we translate this sentence as “Rabbit!” Whether the word *gavagai* is to be taken to apply to rabbits, temporal stages of rabbits, or something even stranger to us can be settled only when we can ask questions like “Is this the same rabbit as that?” This cannot be done until we have translated the parts of speech that make up the native system of reference, and since this is part of what we do when we adopt a set of analytical hypotheses, there is more than one way of doing it. For example, the sentence translated as “Is this (the same) (rabbit) as that?” might, on another set of empirically sat-

isfactory hypotheses, be translated as “Is this (a rabbit stage) (of the same series) as that?”

In this way Quine arrives at the principle of the indeterminacy of translation, which says that it is possible to compile incompatible manuals for translating one language into another, all of which fit all observable speech dispositions, and that there is no sense in asking which is the right manual. It is only in exceptional cases that we can talk of the meaning of a single sentence, and when our statements about the world conflict with experience, they do so not individually but as a system. Thus, we have what might be called the Quine-Duhem conventionalist thesis that any statement can be held to be true no matter what is observed, provided that adjustments are made elsewhere in the system; it is from this thesis that Quine infers that it is impossible to make the analytic-synthetic distinction.

Quine believed that his discussion of radical translation reveals the possibility of differences between the conceptual schemes of people that are not empirically conditioned. In the case of two compatriot linguists working independently on the radical translation of a language, one linguist might conclude that he and the native see the world in the same way, as consisting of tables, chairs, ducks, and rabbits, while the other finds that the native speaks of rabbit stages, not of rabbits, and concludes that the native’s outlook is different from his own. Now, in order to determine what the native’s outlook really is, it is necessary to discover which is the correct way of translating the native’s language. But according to the principle of the indeterminacy of translation, it does not make sense even to ask this, and consequently it cannot make sense to ask what the native’s outlook is. It can be shown that the native is in no better position than the linguist here, and it then becomes hard to see the sense of talking about an outlook when there is no conceivable way of discovering what this outlook is. Quine’s position here is not clear. He admitted that these differences of outlook are in principle undetectable and grants that such cultural contrasts are threatened with meaninglessness, but he continued to speak of them.

As radical translation is not known ever to have been undertaken, the absence of incompatible manuals of translation does not count against the principle of indeterminacy. Nevertheless, it might well be contended that until there are more conclusive arguments for it, the principle is to be taken as the incredible consequence of unsound premises. Quine, in discussing meaning, did concentrate on the statement-making function of language, and it has, in fact, been argued that by neglecting

the countless other uses of language, he arrived at a concept of synonymy the inadequacy of which is revealed by the fact that it makes translation indeterminate.

ONTOLOGY

Philosophers have disagreed as to what there is; some have held, for example, that there are only material things, and others have denied this. Quine called such theories “ontic theories” and maintained that they are a part of the sciences distinguished only by extreme generality. Given that there are physical objects, it is the natural scientist who discovers whether there are wombats; and given classes, it is the mathematician who finds out whether there are even prime numbers. Whether there are physical objects and classes, however, is the concern of the philosopher. The integration of established theories, which is one of the aims of scientific work, may lead to any one of many equally satisfactory accounts of the world, each with its ontic theory, and there is no sense in asking which of these accounts is the true one. Thus, Quine took a conventionalist view even of the theses of ontologists.

Today it is commonly maintained that since there is no way of settling an ontic dispute, ontologists have unwittingly concerned themselves with pseudo questions. Quine, in proposing a method of determining the ontic import of a theory, attempted to make such questions decidable and thus real. His method was, in outline, as follows: “ $(\exists x)(x \text{ is a cat})$ ” may be read as “There is an x such that x is a cat” or as “There is something such that it is a cat.” According to Quine, anyone who makes this statement is thereby committed to the existence of cats. The statement consists of the existential quantifier “ $(\exists x)$,” the predicate “— is a cat,” and an “ x ” that works like a pronoun and is needed in any but the simplest cases to show under which quantifier a predicate comes. If we add to this equipment such truth-functional words as “*and*” and “*not*,” we can make statements like “ $(\exists x)(x \text{ is a book, and } x \text{ is boring})$, and $(\exists x)(x \text{ is a book, and } x \text{ is not boring})$.” This is a paraphrase of “Some but not all books are boring,” which, it is alleged, reveals the ontic import of this statement. Bertrand Russell, Quine, and others have suggested similarly revealing paraphrases of general hypotheticals, of statements containing proper names, and of statements containing such descriptive phrases as “the prime number between 5 and 11.” Quine contended that in adopting any theory, we commit ourselves to the existence of certain entities and that by translating the theory into a language in which the only formal devices

are predication, quantification, and truth-functional composition, we make these commitments explicit.

ONTIC COMMITMENTS. The commitments revealed in the above manner are incurred when certain words are used in certain ways. We are, according to Quine, committed to the existence of physical objects because of the ways in which physical object terms function in our language. In contrast, we are not committed to such objects as “sakes,” because even though we do some things for the sake of others, “sake” functions in only a few of the ways in which a term does. When constructing theories, we are, within limits, free to decide what expressions will function as terms, and by such decisions we might commit ourselves to the existence of atoms, for example, but not to that of meters. We accept the reality of physical objects more readily than we do that of atoms because typical sentences about physical objects are more closely associated with sensory stimulation than are typical sentences about atoms. By this criterion sense data are even more acceptable than physical objects, but this is counteracted by the fact that sense data are a less satisfactory basis for an account of the world. On the grounds of utility for theory, classes are to be preferred to attributes and sentences to propositions.

Many would maintain that it is only when Quine is discussing the considerations that influence ontic decisions that he tackles philosophical problems, and that he does this in a way he himself admitted to be sketchy. He does this sketchily because it has been done in detail by others to whom he refers, and believing that ontologists must take account of scientific theories, he is especially interested in working out how this is to be done. Perhaps the major philosophical problem raised by Quine’s proposed criterion of ontic commitment is that of the nature of this commitment: I may know what it is like for a nation to be, or not to be, committed to an isolationist foreign policy, but what is it like to be, or not to be, committed to the existence of physical objects?

REGIMENTATION OF ORDINARY LANGUAGE. The regimentation of language serves purposes other than that of revealing ontic commitments. The logic of ordinary language is difficult to formulate, and consequently it is more economical to theorize in a language that is ordinary except in its logical parts, which are designed to facilitate deduction. And if there are fewer kinds of construction and less obscurity in a regimented language, then in moving into it we simplify and clarify our conceptual scheme.

Because of misgivings about synonymy Quine cannot maintain that for an ordinary-language sentence to be replaced by a regimented one, the two must be synonymous. Indeed, we may be making the replacement just because one sentence is ambiguous and the other is not. Paraphrase into a regimented language consists, he maintains, of replacements that, in certain contexts, forward certain programs. Against this it has been argued that for any two sentences there will be a program that is forwarded by replacing one with the other, and consequently Quine's notion of paraphrase is vacuous unless contexts and programs can be specified. If this can be done, however, the notion of sentence synonymy can be derived. This notion is no less satisfactory, and no more difficult to make adequate sense of, than the notion of paraphrase, without which Quine cannot talk of putting theories into a regimented language.

The bulk of Quine's philosophical work was published after 1947. By 1960 he had combined into a coherent position theses some of which were first put forward ten years earlier. Between 1947 and 1960 certain changes in his views occurred. From declaring, in 1947, that he did not believe in abstract entities, he had come not only to accept such entities but also to claim that he had always done so; from counting phenomenalism, in 1948, as a conceptual scheme suitable for certain purposes, he came to reject it; and from maintaining, in 1951, that in the face of recalcitrant experience we could change our logical laws, he had apparently come to hold that there is nothing that would count as changing our logical laws.

Quine's status as a philosopher never depended upon the number of people who agreed with him. On the contrary, the sign of his achievement is the valuable discussion he provoked by his persistent and penetrating attacks on analyticity and related notions and by his unfashionable conviction that philosophers want to discover what reality is like.

Bibliography

The topics of the two main sections above were first treated in detail in "Two Dogmas of Empiricism" (1951) and "On What There Is" (1948), reprinted in Quine's *From a Logical Point of View* (Cambridge, MA: Harvard University Press, 1953). A definitive statement of Quine's position, including an exposition of the indeterminacy thesis, is in his *Word and*

Object (New York: MIT Press, 1960), in which a list of Quine's many other philosophical publications will be found. His views on analyticity and logical truth are briefly stated in his "Mr. Strawson on Logical Theory," in *Mind* 62 (1953): 433–451. Important earlier articles are his "Truth by Convention," in *Philosophical Essays for Alfred North Whitehead* (New York: Longmans, Green, 1936), reprinted in Herbert Feigl and Wilfrid Sellars, eds., *Readings in Philosophical Analysis* (New York: Appleton-Century-Crofts, 1949), and "Steps toward a Constructive Nominalism," in *Journal of Symbolic Logic* 12 (1947): 105–122, which he wrote with Nelson Goodman.

Among the many discussions of Quine's views are the following, which are the sources of critical points made in this article. H. P. Grice and P. F. Strawson, "In Defence of a Dogma," in *Philosophical Review* 65 (1956): 141–158, defend the analytic-synthetic distinction. P. F. Strawson, "Propositions, Concepts and Logical Truths," in *Philosophical Quarterly* 7 (1957): 15–25, is an attack on Quine's notion of logical truth. Comments on indeterminacy are made in L. J. Cohen, *The Diversity of Meaning* (London: Methuen, 1962), pp. 67–74. Quine's views on ontology are criticized by G. J. Warnock in "Metaphysics in Logic," in *Essays in Conceptual Analysis*, edited by A. G. N. Flew (London: Macmillan, 1956), pp. 75–93, and from a different standpoint in Rudolf Carnap, *Meaning and Necessity* (Chicago: University of Chicago Press, 1947). The relation between conventionalism and the analytic-synthetic distinction is discussed in G. H. Herbert, "The Analytic and the Synthetic," in *Philosophy of Science* 26 (1959): 104–113. Some points made above are also developed in C. F. Presley, "Quine's *Word and Object*," in *Australasian Journal of Philosophy* 39 (1961): 175–190.

C. F. Presley (1967)

QUINE, WILLARD VAN ORMAN [ADDENDUM]

Willard Van Orman Quine, the Edgar Pierce Professor of Philosophy Emeritus, at Harvard, author of twenty-one books and scores of journal articles and reviews, made many significant contributions to metaphysics, epistemology, philosophy of language, philosophy of science, philosophy of mind, logic, philosophy of logic, and set theory, and ethics (and ethical theory). These contributions are of a stature that firmly places Quine among the titans of twentieth-century Anglo American philosophy.

In most of his publications following *Word and Object* (1960), Quine sought to sum up, clarify, and expand on various themes found in that book. Quine can occasionally be seen changing his mind regarding some detail of his prior thought, but by and large he remains remarkably consistent.

NATURALISM

The keystone of Quine's systematic philosophy is naturalism. Roughly, naturalism is the view that there is no suprascientific justification for science *and* that it is up to science to determine both what there is (ontology) and how we know what there is (epistemology). Moreover, Quine maintains that the best current science tentatively and fallibly plumps for a physicalist ontology and an empiricist epistemology.

ONTOLOGY: PHYSICALISM. Since he maintains that what a (formalized) theory says there is is determined by the range of values of the bound variables of that theory, and since the bound variables of the best current scientific theory of the world (*viz.*, physics) range over both physical objects and numbers, then, given his naturalism, Quine's physicalism embraces both concrete objects and abstract objects. He is a scientific realist regarding (observable and unobservable) physical objects and a Platonic realist regarding numbers (or sets). However, in *Pursuit of Truth* (1980) Quine downgrades the philosophical importance of ontology, including physicalism. He does so because of ontological relativity (*i.e.*, indeterminacy of reference). The thesis is that a theory's ontology can be supplanted *salva veritate* by any one-to-one mapping of it. Ontological relativity thus engenders an attitude of indifference toward various equally apt ontologies for a given theory, including physical theory so called. At the same time it highlights the importance of a theory's ideology, that is, its lexicon of predicates. The philosophical point of Quine's thesis is, then, that what a theory says there is is less important to our understanding of the world than what a theory says about what there is.

There are two further senses in which Quine may be said to be a physicalist. First, as expected, he rejects Cartesian dualism of mind and body in favor of materialism. In this regard, he endorses Donald Davidson's anomalous monism: token identity, type diversity. Second, he is a physicalist in the sense in which physicalism is opposed to phenomenalism in epistemology (see below).

EPISTEMOLOGY: EMPIRICISM. If the best current scientific theory (tentatively and fallibly) proffers a physicalist answer to the question of what there is, then what does it proffer in response to the question of how we know what there is? The answer is, in a word, empiricism. Quine maintains that it is a finding of science that all that we come to know about the world begins with the activation of our nerve endings.

So, Quine endorses the naturalization of both ontology and epistemology. And although he downgrades the philosophical importance of ontology, he maintains the philosophical importance of epistemology. The central question of epistemology, according to Quine, is How do we acquire our theory of the world and why does it work so well? Any answer to this question must explain the relation between one's empirical data (the "meager input") and one's theory of the world (the "torrential output"). Much of what Quine wrote after *Word and Object* is, ultimately, devoted to answering this question. His own distinctive answer may be called externalized empiricism in order to differentiate it from approaches of other naturalized epistemologists (*e.g.*, Donald Davidson). Quine's empiricism is externalized in the sense that he takes sets of activated nerve endings as his data and sets of sentences as his theory of the world (as opposed, say, to impressions and ideas, respectively).

In Quine's hands, the general relation, R_1 , holding between sets of activated nerve endings and sets of sentences gets analyzed into two relations. There is the causal relation, R_2 , holding between holophrastically construed observation sentences and their respective patterns of activated nerve endings, and there is the logical relation, R_3 , holding between those same observation sentences, now analytically construed, and standing sentences. Quine schematizes how the child or the race, beginning with verbal responses conditioned to their respective patterns of nerve endings (R_2), could have gone on to achieve verbal reference to bodies, substances, unobservables, and abstract objects (R_3). Moreover, his account of R_3 explains how observation sentences are logically related to theoretical sentences in such a way that no bridge principles are needed for linking observation and theoretic sentences. His account also highlights the hypothetico-deductive method of prediction and falsification and the moderately holistic character of theory revision.

RECIPROCAL CONTAINMENT. Externalized empiricism is Quine's contribution to answering the central epistemological question of how we acquire our theory of the world and why it works so well. As such, his epistemology (empiricism) "contains" his ontology (physicalism): *nihil in mente quod non prius in sensu*. However, Quine's epistemologizing always takes place within some accepted theory of the world (the best one he can muster at the time), so his epistemology (empiricism) is itself contained within his ontology (physicalism). This latter containment is the central lesson of naturalism: There is no first philosophy. It is this latter containment that also

makes Quine's epistemology such a radical departure from the tradition.

CHANGES OF MIND

Even though Quine's thought has been remarkably consistent since his first works appeared in the 1930s, he changed his mind on a few important matters. First, he downgraded the importance of ontology, discussed above. Second, in the context of radical translation, Quine dropped the idea that the linguist can translate the native's "Gavagai" as her own "Lo, a rabbit" just in case the native's stimulus meaning for "Gavagai" is approximately the same as the linguist's for "Lo, a rabbit." The problem is with making scientific sense of this "implicit homology assumption" regarding different people's nerve endings. Quine changed to the position that the linguist can translate the native's "Gavagai" as her own "Lo, a rabbit" just in case the linguist can empathize with the native to the extent that she can confidently conjecture that, were she in the native's position when he uttered (or assented to) "Gavagai," then she would have done likewise for "Lo, a rabbit." In this way the linguist is (tentatively) equating the native's "Gavagai" with her own "Lo, a rabbit" without relying on an implicit homology assumption. Third, since, according to Quine's externalized empiricism, the meager input underdetermines the torrential output, then it is conceivable that there could be two (or more) global theories of the world that are empirically equivalent, logically compatible, equally simple, and so forth. Would both be true? Quine's empiricism encourages an ecumenical response: Both would be true. His naturalism encourages a sectarian response: Only one would be true. Quine himself vacillated on the issue but eventually endorsed the sectarian response. This suggests that his commitment to naturalism runs deeper than his commitment to empiricism.

Bibliography

WORKS BY QUINE

Among Quine's post-*Word and Object* books that bear directly on the topics discussed here are:

The Ways of Paradox and Other Essays. New York: Random House, 1966; enlarged ed., Cambridge, MA: Harvard University Press, 1976.

Ontological Relativity and Other Essays. New York: Columbia University Press, 1969.

Roots of Reference. La Salle, IL: Open Court, 1974.

Theories and Things. Cambridge, MA: Harvard University Press, 1981.

Other of Quine's later books of interest are:

Set Theory and Its Logic. Cambridge, MA: Harvard University Press, 1963; rev. ed., 1969.

Philosophy of Logic. Englewood Cliffs, NJ: Prentice Hall, 1970; Cambridge, MA: Harvard University Press, 1986.

The Web of Belief. With J. S. Ullian. New York: Random House, 1970; rev. ed., 1978.

The Time of My Life. Cambridge, MA: MIT Press, 1985.

Quiddities. Cambridge, MA: Belknap Press of Harvard University Press, 1987.

WORKS ON QUINE

The secondary literature on Quine is immense and still growing. It includes:

Barrett, R., and R. Gibson, eds. *Perspectives on Quine*. Cambridge, MA: Blackwell, 1990.

Davidson, D., and J. Hintikka, eds. *Words and Objections*. Dordrecht: Reidel, 1969.

Gibson, R. F., Jr. *The Philosophy of W. V. Quine: An Expository Essay*. Tampa: University Presses of Florida, 1982.

Hahn, L. E., and P. A. Schilpp, eds. *The Philosophy of W. V. Quine*. La Salle, IL: Open Court, 1986.

Hookway, C. *Quine: Language, Experience, and Reality*. Stanford, CA: Stanford University Press, 1988.

Romanos, G. D. *Quine and Analytic Philosophy*. Cambridge, MA: MIT Press, 1983.

R. F. Gibson (1996)

RACISM

“Racism” is the doctrine that one group of men is morally or mentally superior to another and that this superiority arises out of inherited biological differences. Of the modern theories aimed at dividing one portion of humanity from another, it is the most morally reprehensible and the least substantially based. Nationalism has a certain rationale in the existence of nation-states, and it does not, at least not necessarily, imply the inferiority of one nation to another. The various doctrines of the struggle between economic classes can point to a wide assortment of empirical evidence in support of their claims; in the Marxist version the exploiting capitalist is as much a victim of the capitalist system as is the exploited proletariat, and the eventual overcoming of all class distinctions is a moral aim as well as a prophesied event. The tenets of racism, however, lead to moral conclusions that contradict many of the most generally accepted civilized standards and have notoriously led to what on ordinary grounds are inconceivable crimes. It might be claimed that ordinary standards are mistaken and that, for example, it was morally imperative that the Nazis exterminate the Jews—if racist claims had a substantial factual basis. Fortunately for ordinary moral standards, if not for the

exterminated Jews and other victims of racial persecution, the tenets of racism are not merely unsubstantiated by the facts but in large measure contradicted by the facts.

Nor have the most important racist theorists been equipped to judge the alleged facts on which they based their claims. The question of race is an enormously complex one, and a judgment on it requires a synthesis of materials from history and prehistory and from a wide variety of biological, anthropological, and psychological disciplines, but primarily from genetics. Many of the necessary facts have only recently become available, and major questions remain unanswered. Yet most racist theories were put forth prior to the accumulation of this evidence, and even most contemporary racist theories are based on outdated biology. Furthermore, most racists—Houston Stewart Chamberlain, with his varied but erratic education, is a possible exception—have lacked the scientific training required to judge whatever evidence was available at the time they wrote. And until a racist theory can be substantiated to a very high degree of probability, the unpalatability of the conclusion that there are inequalities in the capacities of groups of men requires that the theory be rejected.

OUTLINE OF THE THEORY

Although there are many variations on the racist theme (the number of contradictions among racist claims, notably about which are the privileged races, is enough in itself to cast doubt on the tenability of the whole racist enterprise), a model set of racist tenets, divisible into three groups of claims, can be isolated.

The first group starts with the premise that humankind is now, has been in the past, or ought to be in the future divided up into biologically distinct groups. The different tenses must be distinguished because in some instances the claim is made that the superior race is not now in existence but should be bred from the “best blood” among various existing groups. This claim is the link between racism and eugenics, but although eugenicists often fall into racist language or hold racist beliefs (Sir Francis Galton, the founder of eugenics, rated blacks as about two grades below the Anglo-Saxon “race,” and the British pragmatist philosopher F. C. S. Schiller supported both eugenics and the English fascist Sir Oswald Mosley), the connection between the two theories is not inevitable.

The distinction between groups of humankind is held to be based on the common biological heredity of the members of each group. Among the biological distinctions between groups are inherited capacities for certain cultural activities—some races, it is claimed, are more warlike than others, some more musical, others predestined to be dominated. These are factual claims, seemingly open to confirmation or refutation by a scientific examination of the evidence, and the evidence seems overwhelmingly against every one of them. Someone who upheld these views would not necessarily be a racist, but they are essential to the racist position.

In a class by itself is the claim that the mechanism of transmission of group characteristics is the blood. Of all racist claims this is the one most surely refuted, and it would seem to be inessential to the doctrine. Yet the insistent stress on this claim even in the face of overwhelming evidence of its falsity is an index of the nonrational sources of racist thinking. Theories of inheritance through the blood, of blood kinship, of bluebloods, and of good and bad blood are survivals of age-old prescientific thought, on the same order as the view that the soul is the breath.

The final set of doctrines are essential to racism and distinctive of it. Not only are human groups different from one another but some are “better,” “stronger,” “higher,” or “more creative” than others—physically,

intellectually, or morally. (The proponent of a particular racist doctrine quite naturally almost always identifies himself with the race he judges superior. Thus, Comte Joseph Arthur de Gobineau, who was born in the south of France and who placed the “Nordic race” at the pinnacle of humanity, devoted considerable research to proving his own descent from the Viking Otto Jarl; the British-born, French and Swiss-educated Chamberlain, who espoused Aryan or Teutonic superiority, included the contemporary English—and the Slavs and Celts—among the Teutons.) The higher race or races, it is claimed, have a moral right to dominate, to enslave, or even to eradicate the lower races. Finally, higher and lower races should not intermarry. Race mixture, or “mongrelization,” is against nature. For the superior race it can lead only to the lowering of standards and to racial degeneration. It would seem that race mixture would improve the “lower” race, but this is generally denied either on biological or on historical grounds. Thus, Chamberlain held that the “lower” Jewish race was not improved by an alleged ancient admixture of Aryan blood, which came too little and too late.

CRITICISM

No complete examination of the fallacies of racist doctrines can be presented here. What seems most important is that there are not now and, so far as anthropological evidence shows, have never been any pure races of men and that the very concept of race as applied to groups of human beings is suspect. In the vast number of its traits humankind is one, and there has been constant intermarriage and a consequent diffusion of genetic traits throughout the species. There are obvious dissimilarities among groups of people, but these differences more or less gradually shade off into one another; it is a question of statistical predominance of certain physical or physiological traits in a population rather than of sharply defined group differences.

Estimates of the number of genes in man range from 10,000 to 100,000, whereas the number of genes that control skin color, shape of lips and nose, and hair form are few. Racists want to correlate these obvious differences—which in themselves are purely statistical and thus no certain guide to the ancestry of a particular person—with differences in innate inheritable mental characteristics. Yet the evidence is against any such correlation. Each gene or gene cluster, except for certain linked genes, is inherited individually; on the average, half comes from the father and half from the mother. The number of possible combinations of ancestral genes is astronomical, and the

question whether specific mental characteristics are linked with a particular genetic heritage can almost certainly be answered in the negative for human beings, if not, perhaps, for certain domestic animals.

In any case, humankind has apparently been faced with an environment that puts a premium on intelligence, and there seem to be no detectable group differences in intelligence. It is practically impossible to devise a satisfactory test to determine whether there are biological differences in intelligence. In most cases the available methods of classifying by ancestry those to be tested are quite fallible. It is equally difficult to find two groups genetically distinct and culturally alike, and intelligence tests are quite generally distorted by cultural factors and place a premium on particular cultural achievements that obscures any possible genetic factors in the results.

Finally, if there were any evolutionary reasons for thinking that some race was at one time constitutionally better fitted to one environment than another, the rate of human cultural change is such that this supposed superiority would have been insignificant for many centuries. There is no reason to think that one group of humankind is mentally or physically better fitted than another to cope with the complexities of modern urban civilization and an internationally dispersed technology.

To the above summary and inadequate account of the biological claims that contradict racism should be added the overwhelming historical evidence of constant migrations and intermarriages of human groups and the highly probable inference that movement and mixture was also the rule during the prehistory of the human species. This has been especially true of the two alleged races most notoriously prominent in racist literature, Aryans and Jews. The Aryan is generally presented as a pure and superior race and the Jewish "race" as inferior, contradictorily characterized as both pure and bastardized, often by the same author. However, there neither is nor could be evidence that either race is more or less "pure" than the other. Each group is an amalgam of people of varied ancestry, and mixture has produced no apparent genetic debilitation of the sort that racists inveigh against when they deplore the "mongrelization of the race." Cultural differences exist between Germans and Jews, but there are likewise cultural differences between different groups of Germans and between groups of Jews, as well as cultural similarities between German and Jewish groups. To assign these likenesses and similarities to race rather than to a vast complex of recognized socio-cultural factors is to ignore a great bulk of historical evidence.

THE IRRATIONALISM OF RACISTS. Arguing with a proponent of racism is like arguing with someone who would today claim that the earth is flat and at the center of the universe. The evidence that the earth is round is so overwhelming, and so bound up with our very conception of what physical science is, that in the face of someone who claims that the earth is flat we can only point helplessly at the great body of scientific factual claims and scientific laws and ask, "But don't you see?" Similarly, when we are faced with the claims of a racist who persists in his doctrine in the face of our very notions of what constitutes biology and what constitutes historical research, we have no common ground for argument with him. An extreme but typical racist statement can be used as an example:

It is established for all time: "alien albumen" is the sperm of a man of alien race. The male sperm is partially or completely absorbed by the female and thus enters her bloodstream. One single cohabitation of a Jew with an Aryan woman is sufficient to poison her blood forever. Together with the "alien albumen" she has absorbed the alien soul. Never again will she be able to bear purely Aryan children ... they will all be bastards. (Julius Streicher, quoted in Quentin Reynolds, Ephraim Katz, and Zwy Aldouby, *Minister of Death*, New York, 1960, p. 150)

To someone with the most elementary acquaintance with contemporary biology it is unnecessary to point out the false assumptions and false statements in this quotation. But to refute the argument in a way that would satisfy its maker is impossible, because he denies the very grounds on which a scientific refutation as we understand it could be based.

The racist views in Adolf Hitler's *Mein Kampf* likewise seem based on a different biology from the one we know, but in Hitler's thought there is an added historical dimension. The picture Hitler draws of the sociopolitical situation in Germany and Austria during his own lifetime is often shrewd, but it is open to rational criticism: he makes factual claims that can be shown to be historically untrue and historical interpretations that can be challenged by an appeal to evidence and probability. His picture of the Aryans as the only culture-creating people, whose presence in a certain area at a certain time can be demonstrated simply because cultural innovation must have taken place then and there, bears no relation to what we know of the movements of peoples or to our notions of probability. In the chapter "Nation and Race," Hitler

uses few examples, and when examples are given they are used tendentiously to show what they could not prove. Thus, the culture of contemporary Japan, he claims, is the product of European stimulation: It is Western culture and technology with Japanese trimmings. Without continued infusions of Western culture, the culture of contemporary Japan is doomed to decay, and the culture found in Japan by Western explorers must itself have been the ossified remnants of some earlier, but forgotten, Aryan invasion. Hitler's arguments do not generally reach even the level of this one, circular as it is. Yet to show that no such invasion took place in historical times, and probably could not have taken place in prehistoric times, seems no answer to Hitler's claims. The picture he presents of the past is a deliberately mythical one, on a deliberately mythical time scale that bears no apparent relation to the known events and temporal ordering of history. In the absence of such relationships, all appeals to facts become irrelevant, and facts are notably absent from the argument.

RACISM OUTSIDE GERMANY

Although racism as a fully articulated doctrine and the central feature of official policy is notoriously associated with Germany, it has been powerful elsewhere. It was among thinkers of the French Enlightenment—Comte de Boulainvilliers, Comte de Buffon, and Baron de Montesquieu—that the concept of race was first made explicit and the germs of racism were implanted. Gobineau, in the mid-nineteenth century, was the true originator of the doctrine of racism, and throughout the nineteenth century and later, French thinkers vied with one another to show their descent from Gauls, Romans, Gallo-Romans, Celts, or Teutons and the superior Frenchness of one of these purported races over another.

In the United States and England also racism has flourished, and in these countries the complex interconnection of racist doctrines with social and economic factors is most apparent. In English thought racism has been mainly a concomitant of imperialism. The influx of darker-skinned peoples from the Commonwealth has led both to widespread resentment and to the expression of racist sentiments, but not as yet to any new fully developed racist theories. In the United States racism first arose in the South as a defense of slavery, was invoked as a justification of American imperialist expansion into the western Pacific and the Caribbean and for the restriction of the immigration of "undesirable" stock into the United States, and arose again as a defense of segregation.

Twentieth-century arguments that blacks were biologically inferior are not essentially different from earlier ones, of which Samuel Cartwright's "The Prognathous Species of Mankind" (1857) is an example. The argument moves from stressed and exaggerated physiological differences between blacks and whites to the claim of broad mental differences. Features of the "typical negro" are closer to "the simiadae and the brute creation" than to whites. The standard black color is a shiny, oily black, and lighter colors are the result not of intermixture with whites but of sickness or degeneration. In "the bleaching process of bad health or degeneration" even the pigment of the iris is lost, and the degenerate Negro is clairvoyant at night. The Negro does not have real hair: "the shaft of each hair is surrounded with a scaly covering like sheep's wool, and, like wool, is capable of being felted. True hair does not possess this property.... the negro approximates the lower animals in his sense of smell, and can detect snakes by that sense alone. All the senses are more acute, but less delicate and discriminating than the white man's." Natural history, like the Bible, "proves the existence of at least three distinct species of the genus man, differing in their instincts, form, habit, and color. The white species having qualities denied to the black—one with a free and the other with a servile mind—one a thinking and reflective being, the other a creature of feeling and imitation, almost void of reflective faculties, and consequently unable to provide for and take care of himself."

Several racial theories, notably those of Madison Grant and Lothrop Stoddard, reflected the growing awareness among the descendants of earlier groups of immigrants to the United States of the changing national origins of later groups. The works of these men both promoted the fear of the ultimate extinction of the "white race" (which was often meant to exclude southern and eastern Europeans) by rising birth rates among Asians and Africans and influenced the restrictive immigration laws of the 1920s. But it is doubtful whether these or later writers have added anything substantially new to the racist theses.

RACIST WRITINGS

The fountainhead of racist doctrines is Count Joseph Arthur de Gobineau's four-volume *Essai sur l'inégalité des races humaines* (Paris, 1853–1855); Vol. I has been translated by Adrian Collins as *Essay on the Inequality of Races* (London and New York, 1915). The first two volumes were also published at Philadelphia as early as 1856 in a translation by H. Hotz and with an introduction by Josiah C. Nott, both of whom were propagandists for slavery. For an early refutation of Gobineau's views based on moral grounds, see Alexis de Tocqueville's correspondence in his "The European Revolution" & *Correspondence with Gobineau*, edited by John Lukacs (Garden City, NY: Doubleday, 1959).

Richard Wagner published his anti-Semitic essay, "The Jews in Music," in 1850. Wagner later became an enthusiastic supporter of Gobineau, and Gobineau of Wagnerism. Representative writings of Wagner on race are available in *Wagner on Music and Drama*, compiled by Albert Goldman and Evert Sprinchorn (New York, 1964). Also important in disseminating Gobineau's views in Germany was Ludwig Schemann, founder of the Gobineau-Verein, translator, editor, and biographer of Gobineau, and author of such racist works as *Die Rassenfrage im Schrifttum der Neuzeit* (Munich, 1931).

Houston Stewart Chamberlain, Wagner's son-in-law, ranks with Gobineau as a race theorist; the two-volume *Die Grundlagen des neunzehnten Jahrhunderts* (Munich, 1899), his major work, was translated by John Lees as *The Foundations of the Nineteenth Century*, 2 vols. (London and New York: J. Lane, 1911). Chamberlain influenced both Adolf Hitler's *Mein Kampf* (2 vols., Munich, 1925–1927) and Alfred Rosenberg's *Der Mythus des 20. Jahrhunderts* (Munich, 1930).

The term *Aryan* was popularized by Friedrich Max Müller as a label for the speakers of the hypothetical language from which Indo-European languages were allegedly descended. Although Müller later denied that the term had any racial significance, the romantic claim that language expresses the soul of the race made the identification of Aryan speakers with an Aryan race almost inevitable, and Müller's own writings abound in such identifications. See, for example, *Lectures on the Science of Language*, 2 vols. (London: Longman, Green, Longman, and Roberts, 1861–1864).

In defense of slavery on racial grounds, see, in addition to Cartwright's essay, Josiah Nott's *Types of Mankind* (Philadelphia, 1854), parts of which are reprinted with Cartwright's essay and other writings in *Slavery Defended: The Views of the Old South*, edited by Eric L. McKittrick (Englewood Cliffs, NJ: Prentice-Hall, 1963). Other American works are Madison Grant, *The Passing of the Great Race* (New York: Scribners, 1916), and Lothrop Stoddard, *The Rising Tide of Color against White World-Supremacy* (New York: Scribners, 1920).

WORKS ON RACE AND RACISM

Jacques Barzun, *Race: A Study in Superstition*, 2nd ed. (New York: Harper and Row, 1965), is a historical survey. See also Ernst Cassirer, *The Myth of the State* (New Haven, CT: Yale University Press, 1946), Ch. 16, and Hannah Arendt, *The*

Origins of Totalitarianism, 2nd ed. (New York: Meridian, 1958), especially Ch. 6.

Ashley Montague, *Man's Most Dangerous Myth*, 4th ed. (New York, 1964), and Ashley Montague, ed., *The Concept of Race* (New York: Free Press of Glencoe, 1964), together survey much of the present relevant biological knowledge and opinion. L. C. Dunn and Theodosius Dobzhansky, *Heredity, Race, and Society*, 2nd ed. (New York: New American Library, 1952), is a clear and useful account of the genetic aspects. Carlton S. Coon, *The Origin of Races* (New York: Knopf, 1962), is a work by a physical anthropologist who believes in the existence of biological differences between human groups that are associated with intellectual differences. Henry E. Garrett, "The Equalitarian Dogma," in *Perspectives in Biology and Medicine* 4 (1961): 480–484, presents a minority view by a former head of the American Psychological Association.

Philip W. Cummings (1967)

RACISM [ADDENDUM]

Racism is the view that (1) the human species is composed of different racial groups, (2) these groups are arranged hierarchically from least to most superior, and (3) superior groups have the right to use inferior groups for the benefit of the superior group. Sexism and speciesism are similarly defined, justifying the right of men to dominate women, and the right of human beings to dominate other species of beings. Before Darwin, racial groups were typically defined in terms of lineage and type: a racial group was the progeny of certain original types, each of which exemplified a distinctive physiology and pattern of behavior. The current status of a racial group was then explained by reference to its ancestral sources. Thus, the democratic and enterprising nature of the English was the result of their Anglo-Saxon heritage, whereas the servile position of Africans was the result of their being the progeny of Ham, cursed by Noah to be servants of servants. Some argued that Africans were not the progeny of Adam and Eve, but were a pre-Adamite lower species to be used for human benefit.

Post-Darwinian biology favored the notion of race as a sub-species—a group within a particular species that is isolated genetically from other members of that species, and as a result develops distinctive morphological and/or behavioral attributes. Africans, Asians, and Europeans look different because they have evolved on different continents and have developed different body types and personalities.

Social Darwinism portrayed evolution as a struggle for existence in which superior races survived and inferior ones perished. Eugenicists hoped to enhance natural

selection by using our knowledge of natural phenomena to reproduce superior human beings and avoid reproducing inferior ones. Polygenecists considered the “lower” races to be of a different species than the “higher” races, and therefore subject to the interests of the higher races. They believed that, like the offspring of horses and donkeys, racial “hybrids” were likely to be infertile and dysfunctional. Even when races were acknowledged to be of the same species, “race mixing” was considered dysgenic and debilitating to the “higher” races. Miscegenation laws prohibiting intermarriage and procreation between different races were considered to be in society’s best interests and therefore good social policy.

The claim that Africans and African Americans have diminished cognitive and moral capacities compared with Europeans and European Americans was often used to justify slavery and segregation. This claim continues to attract adherents who seek naturalistic explanations of skewed racial achievements such as J. Richard Herrnstein and Charles Murray (1994), Michael Levin (1997), and Stephen Kershner (2003). According to Allan Chase (1980), Malthusians held that the diminished intelligence of the “lower races” lead them to bad choices and immoral behavior that worsened their plight and made them among the least well off wherever they were.

Some have argued that research on racial differences perpetuates harm by reinforcing racist assumptions and should be curtailed. But while the results of research on racial differences could be used to harm, such knowledge could also be used to help. If, for instance, it were found that people with high melanin content in their skin responded to a particular chemical compound that affected mental functioning, then it might be possible to manipulate that compound to either boost or retard intellectual performance. Research on racial differences degenerates into racism only when racial differences are believed to establish a hierarchical ranking that is biologically fixed and immutable.

Many now consider the very concept of a race to be an artifact of European expansionism, justifying European domination of African, Asian, and Native American people. On this view, Europeans classified “others” as different races to further the ends of domination, and continued use of racial categories merely reinforces that original aim. Rejecting European economic, political, and cultural imperialism requires that we reject both racism and racialism (i.e., classification by races). In a similar fashion, Marxists consider racism to be an ideological ploy that divides the lower classes so that the European

and non-European proletariat fight one another instead of fighting capitalists.

The Nazis portrayed Jews as an inherently acquisitive and parasitical race that threatened the evolution of mankind. Their mission was to exterminate the “Jewish race” and establish the unchallenged hegemony of the “Aryan race.” In reaction to the atrocities of the holocaust, many scientists and leaders such as Joseph Graves (2001) and Ashley Montagu (1997) marshaled evidence to show that race was a pseudoconcept with no biological validity. On this view, neither the Jews nor the Aryans were races defined by distinct biological differences. Jews typically were biologically more similar to contiguous non-Jews than they were to Jews in distant locales. Moreover, classifying people into races by skin color, hair texture, and other observable characteristics ignores many other features (such as internal proteins and DNA sequences) that could also be used to classify them. Those who argue that there are no races typically cite evidence that genetic variation is greater within traditional racial groups than between them, thus showing that racial groups are not reproductively isolated gene pools.

But other biologists and social scientists, such as Phillip Kitchner (1999), Robin Andreasen (2000), and Neil Risch (2003), have insisted that there is compelling biological evidence for the existence of races. These researchers assert that when human populations are classified in terms of their ancestral geographic origins, there is a high correlation between traditional racial groups and genetic clusters.

However, the question of whether or not races exist is independent of whether racism exists. Just as it is possible for witchcraft to exist even though there are no witches, so it is possible for racism to exist even if there are no races. Some, such as Naomi Zack (2002), argue that if we are to move beyond “racial” animosities of the past, we must cease using racial categories, because they have no biological validity. For Lucius Outlaw (1996) and Alain Locke (1999), continued consciousness of racial distinctions may be linked to pride in cultural achievements made under extreme duress, or to demands for restitution for past and present harms. Whether or not races exist, it should be possible to agree that racism is morally wrong, and that racism should be eliminated.

Racist behavior elevates the interests of members of allegedly superior races over the interests of allegedly inferior races. The existence of racist behavior may be independent of individual intent, as is often the case with institutional racism, where certain procedures and practices harm groups historically considered inferior, even if

the implementers do not explicitly intend such harm. Thus, requirements that are unnecessary for successful performance and recruitment limited to traditional networks often serve to perpetuate the effects of overt and egregious racist acts of the past, even if this is not currently intended by those who implement such policies.

RADBRUCH, GUSTAV

(1878–1949)

Gustav Radbruch was a German legal philosopher whose name and work have become widely known outside Germany only since the end of World War II. During his lifetime, the interests and activities of scholar, politician, and reformer of law were closely intermingled. After World War I, Radbruch became active in the Social Democratic Party and twice served as minister of justice of the Weimar Republic. His principal work was the draft of a new criminal code. Later he held a chair of law at the University of Heidelberg, from which he was dismissed by the Nazi regime. After World War II he was recalled and exercised a predominant influence in the reorientation of German legal education and philosophy until his death.

Radbruch's legal philosophy, generally known as "relativism," is closely akin to the position of his friend and teacher Max Weber. Radbruch believed, like Weber, that values could not be scientifically proved and that they were "a matter of conscience (*Gewissen*), not of science (*Wissenschaft*)," This in no way implied indifference to values. Radbruch differed both from Rudolf Stammler, who sought to formulate a theoretically valid concept of justice, and from Hans Kelsen, who detached legal science altogether from a philosophy of values. Radbruch, while starting from the Kantian distinction of "is" (*Sein*) and "ought" (*Sollen*), was guided mainly by the teachings of Heinrich Rickert and Emil Lask in treating law as a *Kulturwissenschaft*, a science directed to the realization of values. He therefore considered that the task of legal philosophy was to relate legal reality to basic ideas. But the truth of specific ideas and values cannot be scientifically proved. Radbruch instead developed—and applied to numerous specific problems of law—a series of antinomies of legal values. Thus, the Aristotelian idea of distributive justice, which directs equals to be treated equally, says nothing about the perspective from which they are to be characterized as equals or unequals. Justice, which cannot yield objective criteria of equality, must be supplemented by a second value, "utility," and a third, "security." Between these three values there is constant tension. In another perspective, law can be directed to individual values, collective values, or work values. Accordingly, a legal system emphasizes either individualism, collec-

tivism, or transpersonalism. For the first, the ultimate idea is liberty; for the second, the nation; and for the third, civilization.

After the war, Radbruch recoiled from the extremes of tolerance—as practiced by the Weimar Republic during the rise of the Nazi movement—having witnessed the unprecedented barbarism of the Third Reich, which was largely covered by a formal notion of law. He tentatively turned to a moderate natural-law philosophy, holding that in certain extreme cases a contradiction between positive law and justice might reach such an intolerable degree that the law as unjust law (unlawful law, *unrechtes Recht*) must cede to the higher demands of justice. Radbruch died before he could elaborate his thesis beyond the postulate that special courts should be empowered to adjudicate the validity of laws.

RADISHCHEV, ALEKSANDR NIKOLAEVICH

(1749–1802)

Aleksandr Nikolaevich Radishchev was the leading social critic and philosopher of the Russian Enlightenment. He was born in Moscow, the son of a prosperous landowner, and was educated in Moscow, in St. Petersburg, and, from 1766 to 1771, at the University of Leipzig. At Leipzig he studied under the Leibnizian Ernst Platner and read widely in current French philosophy. Upon his return to Russia he pursued a successful career in the civil and military service until 1790, when his radical work *Puteshestvie iz Peterburga v Moskvu* (St. Petersburg, 1790; translated as *A Journey from St. Petersburg to Moscow*) aroused the ire of Catherine the Great and he was exiled to Siberia. Paul I permitted him to return to European Russia in 1796. After the accession of Alexander I, in 1801, Radishchev was appointed to a special legislative commission, but his egalitarian, libertarian proposals went unheeded, and in September 1802 he took his own life in St. Petersburg.

In the *Journey*, Radishchev employed the principles of natural law and the social contract to support a severe critique of Russian social institutions, serfdom in particular. Under the inspiration of Jean-Jacques Rousseau, Voltaire, Guillaume-Thomas-François de Raynal, and other French thinkers, he condemned serfdom as morally wrong and economically inefficient, criticized autocracy, and attacked censorship and other practices that violate men’s natural rights to freedom and equality. He advocated immediate reforms to avert revolution and called generally for enlightenment and “naturalness” in social arrangements, manners, and morals.

In Siberia, Radishchev wrote his principal philosophic work, *O cheloveke, o ego smertnosti i bessmertii* (On man, his mortality and immortality; published posthumously, St. Petersburg, 1809), a close examination of the cases for and against personal immortality. In the end he rejected materialistic denials of immortality in favor of various arguments—from personal identity and the conservation of force, among others—that suggest the existence of an incorporeal soul that survives the body and passes into a more perfect state. In epistemology Radishchev adopted a realistic position and accepted experience as the only basis for knowledge but maintained that in addition to sensory experience there is “rational experience” of the relationships of things and that man “feels” the existence of a Supreme Being. He also maintained that things in themselves are unknowable,

asserting that thought, like the verbal expression it employs, is merely symbolic of reality.

Radishchev's treatise *O cheloveke* was one of the first original philosophic works in the Russian language, and the influence his pioneering social criticism had on Alexander Pushkin, the Decembrists, and subsequent generations of Russian reformers and revolutionaries has led to his being regarded as the father of social radicalism in Russia. He was also a poet of considerable talent.

RĂDULESCU-MOTRU, CONSTANTIN

(1868–1954)

Constantin Rădulescu-Motru, the Romanian philosopher of energetic personalism, studied at the universities of Bucharest, Paris, Munich, and Leipzig. He obtained his doctorate from Leipzig in 1893 with a thesis on the development of Immanuel Kant's theory of causality in nature, published in Wilhelm Wundt's *Philosophische Studien*. In 1904 he became professor of psychology and logic at the University of Bucharest. He founded the journals *Noua Revista Română* (1900), *Studii Filosofice* (1905, after 1920 called *Revista de Filosofie*), *Anale de Psihologie* (1935), and

Jurnal de Psihotehnică (1937), as well as the Romanian Society of Philosophy.

Rădulescu-Motru was the dominant figure in Romanian philosophy from 1905 to 1930. The most articulate expression of his philosophical system is to be found in his *Personalismul Energetic* (1927). Influenced by the work of Wilhelm Ostwald and William Stern, it was an impressive effort to unify the results of natural science, biology, and psychology. Rădulescu-Motru called his system personalistic because the human personality plays the central role within it, and energetic because he considered personality to be the highest form of cosmic energy. The universe is in continuous evolution, and its goal is the creation of energetic personality. Rădulescu-Motru distinguished six stages of the evolutionary process: cosmic energy, adaptation, organic individuality, consciousness, ego, and personality. Personality is both modified and enriched through evolution from the primitive *homo divinans* to *homo faber*. Finally, through Stoicism, Christianity, and science, the energetic personality, the vocational or professional man, emerges. With the achievement of a personality having a total comprehension of the universe, the evolutionary process will come to an end; Nature will have reached its ultimate goal.

RAHNER, KARL

(1904–1984)

One of the most significant Roman Catholic theologians of the twentieth century and a formative influence upon

Vatican II, Karl Rahner was born on March 5, 1904, in the city of Freiburg im Breisgau, Germany, the fourth of seven children in the family of Karl and Luise (Trescher) Rahner. Upon graduation from secondary school at the age of eighteen, Rahner followed in the footsteps of his elder brother Hugo and entered the Society of Jesus; he was to remain a Jesuit his entire life. During his novitiate studies from 1924 to 1927, Rahner was introduced to Catholic scholastic philosophy and to the modern German philosophers. He seems especially to have been influenced by the work of Joseph Maréchal (1878–1944), the Belgian philosopher and Jesuit, whose adoption of Kant's transcendental method in his five-volume work, *Le point de départ de la métaphysique*, had led to somewhat of a breakthrough in the appreciation of Kant's philosophy among neo-Scholastics. Maréchal was known as the "father of transcendental Thomism" for his use of St. Thomas Aquinas's epistemology in an attempt to demonstrate that the metaphysical world Kant had secured for practical reason was already inherent in the theoretical.

After teaching Latin at the Feldkirch Novitiate, Rahner studied theology at Valkenburg in the Netherlands (1929–1933), where his Christian spirituality was further nurtured through study of patristic and medieval mysticism, and above all of St. Ignatius of Loyola (1491–1556), founder of the Jesuit order and author of the *Spiritual Exercises*. Following ordination to the priesthood in 1932, Rahner commenced study for his doctoral thesis in philosophy at Freiburg, while at the same time attending lectures by Martin Heidegger, whose philosophy of Dasein, or "being in the world," was to be the other primary philosophical influence upon him. His dissertation, a response to Kant's critique of theoretical metaphysics by means of the transcendental Thomism of Maréchal and the existentialism of Heidegger, was rejected by his doctoral director, Martin Honecker, for its departure from more traditional neo-Scholastic interpretations of Aquinas's epistemology, but was later published as *Geist in Welt* (Spirit in the world).

After failing the doctorate in philosophy, Rahner returned to Austria, where he successfully completed his second dissertation, this time in theology, at Innsbruck in 1936 and was appointed as Privatdozent (lecturer) in the faculty of theology of the University of Innsbruck in 1937. That summer he delivered a series of lectures to the Salzburg summer school on the "Foundations of a Philosophy of Religion," later published as *Hörer des Wortes* (Hearer[s] of the word).

When the Nazis abolished the theology faculty (July 1938) and the Jesuit college (October 1939) at Innsbruck,

Rahner left for Vienna, where he did some teaching and served as a consultant at the Pastoral Institute for five years. After a brief stint as a pastor in Bavaria in the final year of the war, he taught dogmatic theology at Berchmanskolleg in Pullach. In 1948 he returned to the theology faculty at Innsbruck, where he was to reside until 1964. There he lectured on a wide variety of topics to later be included in the essays published as *Schriften zur Theologie* (Theological investigations), the first volume of which appeared in 1954. Of particular significance was his scholarly preoccupation with the relationship between nature and grace.

During this prolific period Rahner experienced some difficulties within the Church, beginning as early as 1950 when he was prevented from publishing a book on the Assumption of Mary, and continuing through the following decade until 1962, when he was placed under a censorship regulation from Rome. Suspicions over his orthodoxy subsided, however, when the newly elected Pope John XXIII appointed Rahner as one of the theological experts (*periti*) at the Second Vatican Council, and the censorship upon him was reversed in 1963. Rahner's influence at Vatican II was widespread; particularly noteworthy is his selection as one of the seven theologians who would develop *Lumen Gentium* (Dogmatic constitution on the Church), a document fully explicating the doctrine of the Church, and setting forth explicitly in chapter II the Church's inclusivist stance with regard to salvation.

It was during the Second Vatican Council that Rahner was invited to take the Chair in Christianity and Philosophy of Religion at the University of Munich, where he began teaching in 1964, the same year that a Festschrift, *Gott in Welt* (God in the world) was published in honor of his sixtieth birthday. During his time at Munich, Rahner published a collection of essays in spirituality as the seventh volume of *Schriften zur Theologie*, and together with Edward Schillebeeckx edited the first issue of *Concilium*. In 1967 Rahner accepted the University of Münster's invitation to become Ordinary Professor of Dogmatics and the History of Dogma, where he completed three more volumes of the *Schriften*, before retiring in 1971. Retirement brought him back to Munich, where he prepared *Grundkurs des Glaubens* (Foundations of Christian faith), the most systematic summary of his theology, and to Innsbruck, where in addition to pastoral and moral essays, Rahner worked out the most developed form of his transcendental Christology, and completed the final volumes of the *Schriften*, thus continuing the life

of the diligent scholar until his death in Innsbruck on March 30, 1984.

Rahner has been criticized for a failure to adequately address the problem of evil, especially in light of his experience as a German Catholic living through the Nazi genocide of two-thirds of the Jewish population of Europe. Neither in the above nor in what follows will it be possible to do full justice to the breadth of Rahner's theological output, which covers almost every aspect of religious thought. The focus here is upon Rahner's efforts at *aggiornamento*, or renewal of neo-Scholasticism and the philosophical import of two concepts integral to his theological *weltanschauung*: *Vorgriff auf esse* and *das übernatürliche Existential*.

Geist in Welt focuses upon one of the central problems of philosophy, namely the nature and possibility of metaphysics. In this work, Rahner examines one part of St. Thomas Aquinas's metaphysics of knowledge, specifically that section of the *Summa theologiae* that addresses what appears to sense intuition, *conversio ad phantasmata* (conversion to the phantasm), in light of Kant's critique of speculative metaphysics. Whereas Kant had rejected theoretical knowledge of God in order to secure a place for metaphysics as a practical philosophy, Rahner uses the tools of transcendental and existentialist philosophy, honed through Maréchal and Heidegger respectively, to retrieve the theoretical metaphysics of St. Thomas. *Spirit in the World* is thus Rahner's attempt to demonstrate how, given that human knowledge is wedded to the *a posteriori*, or realm of sensory experience, metaphysics is still possible; and as fraught as the philosophical analysis is, the main arguments are fairly accessible.

Essentially Rahner proffers a teleology of knowledge according to which there is presupposed in every human act of knowing the *Vorgriff auf esse* (the "pre-apprehension of being" in Heideggerian terms), a transcendental awareness of infinite being, or of God, the *a priori* condition without which no individual act of knowing could occur. In every act of knowing then, the individual, or "spirit in the world," has already reached out beyond the world and known the metaphysical. This awareness of God, which is always indirect and shrouded in mystery (since we cannot know God as if God were an object among other realities that are present to us), presupposes the transcendental orientation of the human knower to God, who is both the source and ultimate goal of the human quest for knowledge. To be human is therefore to be in relation to God, since we implicitly affirm the existence of God in every judgment we make, regardless of whether or not we ever formally acknowledge this. *Ipsa*

facto, human existence itself implies the transcendental experience of God for Rahner, thus satisfying not only the transcendental Thomism of Maréchal and the existentialism of Heidegger, but also the Ignation impulse to "find God in all things."

Hörer des Wortes is formally an investigation into the relationship between philosophy of religion and theology. Philosophy of religion, according to Rahner, consists in showing human beings to be the infinite spirits who, because of our nature, are turned toward a possible revelation, or self-communication of God, since revelation for Rahner is always personal, not propositional. God, the personal infinite, chooses human history as the place of transcendent self-communication (a divine self-communication that finds concrete historical expression in Jesus Christ); theology begins with the human person who has become attuned to God's self-communication, a hearer of God's word. In order to make this case, Rahner develops his "transcendental arguments" further and grounds them more fully theologically. By means of a "theological anthropology," a metaphysical analysis of human nature, Rahner proposes *Vorgriff auf esse* as a pre-apprehension of infinite being that also elicits the restless yearning of the human spirit (echoing a desire at least as old as Augustine) for fulfillment in and through that absolute being whose self-communication is both the ground and telos of human existence.

This understanding of the human spirit's desire for transcendent meaning, together with God's ineffable self-communication, later has important implications for Rahner's interpretation of the relationship between nature and grace, a relationship examined through his concept of *das übernatürliche Existential*, the "supernatural existential," first coined during his intervention in the *nouvelle théologie* debate in 1950 but still being worked out as late as 1976 in *Grundkurs des Glaubens*. The debate revolved around whether or not the human orientation toward God was natural or supernatural, and Rahner uses the term "supernatural existential" in an attempt to overcome the tendency in neo-Scholastic theology to dichotomize nature and grace, while at the same time safeguarding the gratuity of God's grace. Once again borrowing from Heidegger's vocabulary, Rahner defines an "existential" as a fundamental element in human existence, and claims that the central and abiding existential of human nature is the unconditional desire for grace and for the beatific vision. At the same time, however, he argues that the very fact of this desire already belies God's self-communication, precisely the meaning of grace for Rahner. In other words, since our very existence is per-

meated with God's constant self-giving, human nature is already grace laden. *Das übernatürliche Existential* ultimately entails the universal human experience of grace, and similar to the *Vorgriff auf esse*, this experience, though wedded to the world, is also transcendental and thus can never be directly or concretely realized.

The ubiquitous nature of the "supernatural existential" also undergirds Rahner's Christian inclusivism, itself a corollary of his philosophy of grace, and arguably the theological stance for which he is best known in non-Catholic circles. For Rahner, because God's gracious self-communication has found concrete historical expression in Jesus Christ, all grace is ultimately the grace of Christ; yet, significantly, Christ's universal grace is not narrowly circumscribed by Christianity. If *das übernatürliche Existential* is a universal given, and just as the *Vorgriff auf esse* is never directly or concretely realized, then it is possible that a person may accept this gift of grace without explicit acknowledgment and regardless of whether or not one is formally Christian. It is for this reason that non-Christians living lives of grace are "anonymous Christians" from Rahner's perspective, a title not intended as a subtle form of Christian supersessionism, but rather as a theologically astute commitment to the view that God's grace is active well beyond the confines of Christianity. The religious inclusivism espoused by Rahner had an ecumenical import that has proven vital to Catholic interreligious dialogue in the post-Vatican II era and that presumably will continue to be relevant to the burgeoning interest in religious diversity among philosophers of religion well into the third millennium

Elizabeth Galbraith (2005)

RAMSEY, FRANK PLUMPTON (1903–1930)

Frank Plumpton Ramsey, the Cambridge mathematician and philosopher, was one of the most brilliant men of his generation; his highly original papers on the foundations of mathematics, the nature of scientific theory, probability, and epistemology are still widely studied. He also

wrote two studies in economics, the second of which was described by J. M. Keynes as “one of the most remarkable contributions to mathematical economics ever made.” Ramsey’s earlier work led to radical criticisms of A. N. Whitehead and Bertrand Russell’s *Principia Mathematica*, some of which were incorporated in the second edition of the *Principia*. Ramsey was one of the first to expound the early teachings of Ludwig Wittgenstein, by whom he was greatly influenced. In his last papers he was moving toward a modified and sophisticated pragmatism.

THE FOUNDATIONS OF MATHEMATICS

A stumbling block in the reduction of mathematics to logic attempted in *Principia Mathematica* has long been its appeal to the so-called ramified theory of types, introduced in order to cope with the paradoxes discovered by Russell and others. The excessive restrictions demanded by the theory of types were mitigated by introducing an ad hoc axiom of reducibility, which Ramsey, following Wittgenstein, held to be at best contingently true. Ramsey was one of the first to argue, following Giuseppe Peano, that many of the notorious paradoxes depended on the use of equivocal semantic notions having no place in mathematics. By introducing the notion of “predicative functions”—roughly speaking, truth-functions permitting infinitely many arguments—Ramsey was able to show that the paradoxes could be avoided without appeal to an axiom of reducibility. In order to improve what he regarded as an unsatisfactory conception of identity in *Principia Mathematica*, Ramsey proposed the wider concept of “propositional functions in extension,” considered as correlations, not necessarily definable, between individuals and associated propositions. Fully elaborated, this view would seem to lead to a markedly nonconstructivistic set theory, which most contemporaries would find unacceptable. Ramsey’s distinction between semantic and logical paradoxes and his rejection of that part of the theory of types that subdivides types into “orders” has been almost universally accepted by his successors.

PHILOSOPHY OF SCIENCE

In a striking paper, “Theories,” Ramsey developed a novel method for eliminating overt reference to theoretical entities in the formal statement of scientific theory. The method consists of replacing, in the axioms of the formal system expressing the scientific theory in question, every constant designating a theoretical entity with an appropriate variable and then applying universal quantification over the propositional matrices thus obtained. Ramsey

was able to show that the conjunction of the universally quantified statements thus derived from the original axioms would have the same observational consequences as the original axiom system. This technique is of interest to philosophers concerned with the ontological implications or commitments of scientific theory.

PROBABILITY

Ramsey sketched a theory of probability considered as measuring a degree of “partial belief,” thereby providing a stimulus to what are sometimes called “subjective” or “personalistic” analyses of probability. His most important idea was an operational test for degree of belief. Suppose somebody, *P*, has no preference between the following options: (1) to receive m_1 for certain, and (2) to receive m_2 if p is true but m_3 if p is false, where p is some definite proposition and m_1 , m_2 , and m_3 are monetary or other suitable measures of utility for *P*. Then *P*’s degree of belief in p is proposed to be measured by the ratio $(m_1 - m_3)/(m_2 - m_3)$ —roughly speaking, therefore, by the betting odds that *P* will accept in favor of p ’s being true, given the relative values to him of the possible outcomes.

GENERAL PHILOSOPHY

Ramsey’s most suggestive idea in general philosophy was that of treating a general proposition, say of the form “all *A*’s are *B*,” as a “variable hypothetical,” considered not as a truth-function (as it had been in his earlier papers) but rather as a rule for judging that if something is found to be an *A* it will be judged to be a *B*—that is, as a formula for deriving propositions in certain ways rather than as an authentic proposition having truth-value. This idea is connected with Ramsey’s unfortunately fragmentary explorations into the connections between belief, habit, and behavior. Ramsey’s papers on facts, propositions, and universals also have not outlived their usefulness.

See also Keynes, John Maynard; Logical Paradoxes; Mathematics, Foundations of; Peano, Giuseppe; Philosophy of Science; Pragmatism; Probability; Russell, Bertrand Arthur William; Scientific Theories; Type Theory; Whitehead, Alfred North; Wittgenstein, Ludwig Josef Johann.

Bibliography

A collection of Ramsey’s work, including previously unpublished papers, was published posthumously as *The Foundations of Mathematics and Other Logical Essays*, edited by Richard B. Braithwaite (London: K. Paul, Trench, Trubner, 1931). This collection has a preface by G. E. Moore, a useful editor’s introduction, and a complete bibliography.

For the definitions of “predicative functions” and “functions in extension,” see especially pp. 39–42, 52–53; Ramsey’s discussion of theories is mainly on pp. 212–236; the generalized betting definition of degree of belief occurs on p. 179.

For discussions of Ramsey’s work, see Israel Scheffler, *The Anatomy of Inquiry* (New York: Knopf, 1963), pp. 203–222, which contains a critical exposition of Ramsey’s procedure for eliminating theoretical terms; Herbert Gaylord Bohnert, *The Interpretation of Theory* (PhD diss., University of Pennsylvania, 1961), further elaboration of Ramsey’s work on the nature of scientific theory; Leonard J. Savage, *The Foundations of Statistics* (New York: Wiley, 1954), which acknowledges indebtedness to Ramsey’s definition of partial belief; and Gilbert Ryle, “‘If,’ ‘So,’ and ‘Because,’” in *Philosophical Analysis*, edited by Max Black (Ithaca, NY: Cornell University Press, 1950; reprinted, New York, 1963), which is a discussion of hypothetical statements as “inference licenses.”

Max Black (1967)

RAMUS, PETER (1515–1572)

Peter Ramus was a logician, educational reformer, and author of many widely used works on philosophy and letters. He was born Pierre de la Ramée in Cuts (Oise), in northern France, the son of an impoverished descendant of a noble family from Liège. After beginning Latin at Cuts, he went to study at Paris, probably between the ages of eight and twelve, and despite grave financial difficulties received his master of arts degree there at the age of twenty-one. His master’s inaugural thesis, according to one still widely circulated but questionable report, was *Quaecumque ab Aristotele Dicta Essent, Commentitia Esse* (Whatever Aristotle has said is a fabrication; the common translation of *commentitia* as “false” is oversimplified).

In 1543, Ramus (he had adopted Petrus Ramus as the Latin form of his name) published two works growing out of his teaching, *Dialecticae Partitiones* (The structure of dialectic,” also titled *Institutiones Dialecticae* [Training in dialectic]) and *Aristotelicae Animadversiones* (Remarks on Aristotle), which violently attacked Aristotle and the university curriculum as confused and disorganized. The university faculty, led largely by doctors of medicine, secured from Francis I a decree forbidding the sale of these books and prohibiting their author from teaching publicly and from writing on philosophy (which included all academic subjects other than grammar, rhetoric, medicine, law, and theology). Ramus, however, quietly continued to teach and write and in 1545 moved to the Collège de Presles in Paris, where he was joined by his earlier asso-

ciate, Omer Talon (Audomarus Talaeus). Ramus soon became principal and dedicated himself, with great success, to promoting more purposeful and effective teaching. In 1547, Henry II lifted the ban against Ramus and in 1551, he appointed him professor of eloquence and philosophy in the body of professors supported by the king, which was later known as the Collège de France; Ramus became its first dean. Earlier an observant Catholic, he embraced the Protestant reform around 1562, withdrawing to Fontainebleau in 1562–1563 during the religious wars and to Rhenish Germany and Switzerland from 1568 to 1570. He returned, however, and was murdered on the third day of the Massacre of St. Bartholomew. Charles Waddington’s assignment of his murder to an academic opponent, the physician Jacques Charpentier, is repeated in many encyclopedia articles but is without demonstrable foundation.

WORKS

Ramus’s published works run to some sixty-odd titles, supplemented by thirteen additional works of Talon, his frequent collaborator. The works of the two men appeared mostly between 1543 and 1650, in nearly eight hundred (at present) known editions and adaptations (some eleven hundred if works published in collected editions are separately enumerated). Besides the pivotal writings on dialectic, or logic, and on rhetoric, Ramus’s works include classical editions and commentaries; lectures on physics, metaphysics, and mathematics; textbooks for grammar, arithmetic, algebra, and geometry; miscellaneous orations and open letters; and the posthumously published *Commentariorum de Religione Christiana Libri Quatuor* (1576), a basically Zwinglian theological work, unoriginal and apparently of little influence. Other works, notably Latin translations from the Greek, remained unpublished at his death. Although most of his writing was in academic Latin, he published a few works in French, including a *Gramere* of the French language (1562) in a reformed spelling that was developed from that of Louis Meigret.

PHILOSOPHY

The striking orderliness of Ramus’s philosophy is superficial and is determined by pedagogical serviceability rather than by insight. His *Dialectica* (French, 1555; Latin, 1556, with subsequent revisions), later called also *Logica*, is the key work in the Ramist canon and appeared in nearly 250 extant editions or adaptations, chiefly Latin. The *Dialectica* grew out of his 1543 works and proposed to supplant the highly complex quantified logic of the

Middle Ages, so objectionable to humanists. Actually, it exaggerates—at times grotesquely—the quantifying drives built up in medieval Scholasticism. Following the *De Inventione Dialectica* of Rudolph Agricola, Ramus reduced all argumentation to one “art of discourse” (*ars disserendi*, a Ciceronian definition common during the Middle Ages), which he called indifferently dialectic or logic. He thus did away with dialectic as a separate art that argues from probabilities and is thereby distinct from a scientific logic, which argues from certainties or necessity.

RHETORIC. By the same token, he also dispensed with rhetoric as a separate argumentative art persuading to action. The Ramist *Rhetorica* (1548), published under Talon’s name but with Ramus’s close collaboration (in some 175 known extant editions or adaptations), reduced rhetoric explicitly to mere “ornamentation,” or the application of tropes and figures, conforming to what had been, in fact, a strong trend in medieval thinking about rhetoric. Like Agricola, Ramus treated logic or dialectic as made up of *inventio* (discovery of arguments for any kind of discourse, from mathematics to poetry) and *iudicium* or *dispositio* (the arrangement of arguments, including for Ramus not only syllogism but also method, likewise referable to any and all discourse). Ramus’s treatment of syllogism varied somewhat from some previous treatments but in no original or insightful way, and he did nothing to advance formal logic. Still, his influence was vast and symptomatic.

LOGIC. In the wake of Scholasticism, logic had a high prestige value even among humanists. Ramus made it accessible to all by withdrawing it, more than even medieval Scholasticism had done, from the scientifically elusive world of sound and word and by associating it more with the sense of vision through overt or covert resort to spatial constructs or models in his teaching. Most notable among these models were the dichotomized divisions, often arranged in bracketed tabular form, for analysis of everything under the sun. One divided a subject into two parts, subdivided each of these into two, then again dichotomized each subdivision, and so on. The resulting structure somehow corresponded both to extramental actuality and to the contents of the mind. The intensified passion for this far-from-new procedure was associated with the new medium of typography, which reproduced these and other spatial constructs with an ease and conviction unknown in a manuscript-oriented civilization.

METHOD. In this climate Ramists gave the term *logical analysis* its first extensive currency and developed concern with method. Between 1543 and 1547 the treatment of method earlier found largely in rhetoric manuals had been transplanted into logic manuals published separately by Johannes Sturm and Philipp Melanchthon. During this period Ramus effected the same transplantation in a pseudonymous 1546 revision of his *Dialecticae Partitiones*, from which method made its way into the *Dialectica* from 1555 on. For Ramus, method prescribed treating any subject by going from the general to the particular, although for special reasons one could use cryptic method, proceeding from the particular to the general. Dichotomization implemented method.

Metaphysics was absorbed or displaced by logic, which Ramus passionately but unconvincingly identified with Plato’s dialectic. Ethics was to be taught by methodized analysis of biography and history, and the physics that had formed so great a part of Scholastic philosophy was replaced, in principle at least, by analytic study of works on natural history such as Vergil’s *Georgics*.

INFLUENCE

Ramus’s realignments involved him in disputes with Antonio de Gouveia, Joachim de Perion, Pierre Galland, Jacques Charpentier, Adrien Turnèbe, Jean Riolan the elder, and Jakob Schegk, disputes protracted after Ramus’s death by hundreds of litigants. Ramist-inspired agitation over method set the stage for René Descartes (who at La Flèche studied a post-Ramist logic textbook with a section on method) and helped make meaningful the application of the nickname “Methodists” to John Wesley’s followers. The modern encyclopedia owes a good deal of its organization to the Ramist and semi-Ramist tradition as represented by polymath organizers of knowledge such as Johann Heinrich Alsted. Ramus’s followers, numbered by the thousands in the sixteenth and seventeenth centuries, were distributed, in descending abundance, through Germany, the British Isles and their American colonies, France, Switzerland, the Low Countries, and Scandinavia. Anti-Ramists such as Nicolas de Grouchy, Everard Digby, and Francis Bacon and Ramists such as Johann Thomas Freige (Freigius), Gabriel Harvey, and John Milton crossbred to produce various syncretists, such as Bartholomew Keckermann, Andreas Libavius, Alsted, and Robert Sanderson. Ramism and its derivatives were particularly popular in Calvinist “middle” or secondary schools for cultural and psychological rather than directly religious reasons: The Ramist account-book interpretation of knowledge and actuality

appealed strongly to the bourgeois mind. Influence in strictly university circles and on speculative thought was more intermittent or indirect, but extraordinarily pervasive.

RASHDALL, HASTINGS

(1858–1924)

The English theologian, philosopher, and historian Hastings Rashdall was born in London, the son of an evangelical clergyman. He was educated at Harrow and at New College, Oxford, where he read Classical Moderations and "Greats." He remained at Oxford two years after graduation, reading philosophy and theology and working on an essay on the history of medieval universities, for which he won the chancellor's prize in 1883. Much of his next twelve years was taken up with expanding this essay for publication in 1895 as a work in three volumes.

In 1883 he left Oxford to become a lecturer at St. David's College, a college for the education of the clergy in Lampeter, Wales, and in December of that year he was appointed a tutor in theology at University College, Durham. In 1889 he returned to Oxford as a fellow of Hertford College and in 1894 was appointed for a year as chaplain and divinity tutor at Balliol, without relinquishing his Hertford fellowship. He returned in 1895 to New College as fellow and tutor and dean of divinity. He retained his New College fellowship but not his tutorship

on his appointment in 1910 as a canon of Hereford Cathedral. He remained in Hereford until 1917, when he became dean of Carlisle, an office he retained until his death.

Rashdall was primarily a theologian and secondarily a philosopher, although he would have been unwilling to draw a clear distinction between the two. His aim was to keep philosophy religious and religion philosophical. Even his history of medieval universities aimed at establishing the rational foundations of religion and ethics, the close connection between the intellectual and spiritual life, and the place of mind in the constitution of the world.

Rashdall justly described himself as "on the left wing of the Church and the right wing of the philosophers." His liberalism in religion and forthright opposition to bigotry kept getting him into trouble with the defenders of orthodoxy. The last years of his life were clouded by the false charge that he denied the divinity of Christ—a charge based on a newspaper misrepresentation of his observation that Jesus never claimed divinity for himself.

Philosophically Rashdall was a personal idealist. Although he held that there is no matter apart from mind—a personal Mind, "in which and for which everything that is not mind has its being"—he rejected monism. Minds are substantial, and every consciousness is exclusive of every other. Individual minds are produced by the eternal Mind, which is God, but are neither included in it nor adjectives of it. In line both with this metaphysical position and with his general distrust of mysticism, Rashdall held our knowledge of God to be inferential.

Rashdall's most important philosophical work is his two-volume *The Theory of Good and Evil*. Although it made no distinctively original contribution to ethics, it is perhaps the best general introduction to the subject written from an objectivist point of view, before the advent of metaethics and the application of philosophical analysis. Rashdall's treatment is thorough and comprehensive, and the book leaves no doubt about the importance for theory and practice of the issues discussed. Although it is not a history of ethics, it includes illuminating expositions and criticisms of theories of classical moral philosophers where these are relevant to the development of his own theme.

Rashdall's emphasis on the value of human personality found expression in his moral theory. Intuitionism, in the sense of acceptance of impersonal moral laws binding independently of their consequences, was wholly

alien to his thought. He was an uncompromising utilitarian, for whom actions are to be judged by their tendency to produce the greatest good or well-being for human beings. There are, indeed, moral intuitions, but they are about the relative value of ends, not about the rightness of rules of conduct. The good that it is the duty of each to produce for all is a personal good but is not confined to pleasure or happiness. Pleasure is only one element that, in interrelation with other mutually modifying elements, including morality, contributes to form an ideally good pattern of life. It was Rashdall who coined the term *ideal utilitarianism* to distinguish this form of the theory from the traditional hedonistic utilitarianism it has generally replaced, partly through his own influence. One advantage of the abandonment of hedonism claimed by Rashdall is that it enables the utilitarian to include in moral judgment the quality of the act itself as well as of its consequences. Thus, the disposition to promote the general good can be taken as itself part of the good to be promoted.

Much of the second volume of *The Theory of Good and Evil* deals with the metaphysical and theological presuppositions of an absolute objective morality. Rashdall held that only in metaphysics can we find an ultimate defense of the validity of moral judgments and that personal idealism has the best chance of supplying it. One postulate of morality is the existence of individual selves to which actions may be attributed; another is the existence of God, as possessing and willing the absolute moral ideal; and a third is immortality. Although he was a determinist, Rashdall escaped having to hold God responsible for evil in human willing because he regarded God not as strictly omnipotent but as limited by those eternal necessities that are part of his own nature.

RATIONAL INTUITION

See *Intuition*

RATIONALISM

The term *rationalism* (from the Latin *ratio*, "reason") has been used to refer to several different outlooks and movements of ideas. By far the most important of these is the philosophical outlook or program that stresses the power of a priori reason to grasp substantial truths about the world and correspondingly tends to regard natural science as a basically a priori enterprise. Although philosophies that fall under this general description have appeared at various times, the spirit of rationalism in this sense is particularly associated with certain philosophers of the seventeenth and early eighteenth centuries, the most important being René Descartes, Benedict de Spinoza, and Gottfried Wilhelm Leibniz. It is rationalism of this type that will be the subject of this entry.

Two other applications of the term should, however, be distinguished.

RATIONALISM IN THE ENLIGHTENMENT

The term *rationalism* is often loosely used to describe an outlook allegedly characteristic of some eighteenth-century thinkers of the Enlightenment, particularly in France, who held an optimistic view of the power of scientific inquiry and of education to increase the happiness of humankind and to provide the foundations of a free but harmonious social order. In this connection "rationalistic" is often used as a term of criticism, to suggest a naive or superficial view of human nature that overestimates the influence of benevolence and of utilitarian calculation and underestimates both the force of destructive impulses in motivation and the importance of such non-rational factors as tradition and faith in the human economy. Jean d'Alembert, Voltaire, and the Marquis de Condorcet, among others, are often cited in this connection. Although there is some truth in these criticisms, the naïveté of these and other Enlightenment writers has often been grossly exaggerated. Also, insofar as "reason" is

contrasted with “feeling” or “sentiment,” it is somewhat misleading to describe the Enlightenment writers as rationalistic, for many of them (Denis Diderot, for example) characteristically emphasized the role of sentiment. Reason was praised in contrast with faith, traditional authority, fanaticism, and superstition. It chiefly represented, therefore, an opposition to traditional Christianity.

Here there are two contrasts with the seventeenth-century rationalism of Descartes and others. First, this rationalism is not characteristically antireligious or non-religious; on the contrary, God in some sense, often in a traditional sense, plays a large role in rationalist systems (although Spinoza’s notion of God was extremely unorthodox, and it is notable that the opposition of reason and faith is important in his *Tractatus Theologico-Politicus*). Second, the view of science held by such Enlightenment thinkers as Voltaire was different from that of rationalism, being much more empiricist. The central contrast embodied in the term *rationalism* as applied to the earlier systems is that of reason versus experience, a contrast that is certainly not present in the Enlightenment praise of the “rational.” Parallel to this difference, there is a difference between the characteristic seventeenth- and eighteenth-century views on the nature and importance of system; the eighteenth century declared itself against the *esprit de système* of the seventeenth century, with its elaborate metaphysical systems, and in favor of an *esprit systématique*, which could be orderly without being speculatively ambitious. (See d’Alembert, *Preliminary Discourse* to the *Encyclopédie* and Condillac, *Traité des systèmes*.)

RATIONALISM IN THEOLOGY

The Enlightenment spirit of rational criticism directed against the supposed revealed truth of the Scriptures also had effects within Christianity itself. In this connection the term *rationalism* is used in a specific theological sense to refer to the doctrines of a school of German theologians that was prominent roughly between 1740 and 1840, and which had great influence on the development of biblical criticism. With their spirit of antismiraculism can be associated Immanuel Kant’s *Die Religion innerhalb der Grenzen der blossen Vernunft* (1793), in which rational morality is the basis of religious belief.

However, the best-known use of “rationalism” in a religious connection is an entirely negative one, in which it stands for an antireligious and anticlerical movement of generally utilitarian outlook, laying great weight on historical and scientific arguments against theism. This

use of the term, a popular rather than a technical one, seems now to be obsolescent, its place being taken by *humanism*.

RATIONALISM VERSUS EMPIRICISM

Rationalism as it will be discussed here is standardly contrasted with empiricism. This contrast (which rests on that contrast between reason and experience which has already been mentioned) is now so basic to the use of the terms that no account can afford to ignore it, and a number of comparisons between views associated with these two outlooks will be made in the course of this entry. It is of course impossible to give a detailed comparison of the two outlooks, and in general comparisons will be introduced incidentally to the account of rationalist ideas. There is, however, one issue, that of innate ideas, which embodies a central disagreement between the two, and regarding which an account merely from the rationalist side would be particularly unilluminating. On this issue the disagreements will be considered in rather greater detail than elsewhere. At the same time, it is hoped that the treatment of this issue will give slightly more insight into the rationalist outlook than can be achieved by what is at other points inevitably a very selective summary of rationalist opinions.

INNATE IDEAS

Descartes distinguished three classes of “ideas” (by which he meant merely whatever it is in a man’s mind in virtue of which he can be said to be thinking of a given thing): adventitious, factitious, and innate. The first type came to the mind from experience, the second were constructed by the mind’s own activity, and the third were created by God together with the mind or soul itself. The last included what were for Descartes the three fundamental ideas of the basic types of substance: God, mind, and matter (or extension). For the most part Descartes argued negatively for the view that these ideas are innate, trying to show that they could not be derived from experience (where this means, fundamentally, sensation).

His argument had two main points. First, the ideas are pure, containing no sensory material; these ideas are not images, reproductions, or copies of sensory experience. Descartes regarded this as fairly obvious in the cases of God and of mind; and he made a particular effort (as in the argument of the wax in *Meditations* II) to establish the same claim for matter. Second, the fundamental ideas implicitly contain, in different ways, some idea of infinity, and in grasping the idea one thereby grasps the possibility of infinitely many and various modifications to which

mind and matter can be subject. In the case of God this argument goes further, for here we grasp an actual infinity of perfections implicit in the idea. The same point, however, holds for all these ideas: The grasp of infinitely many possibilities must transcend what has been given to us in experience, since experience could have given us at best only a limited set of such conceptions, corresponding to what had actually been experienced.

Even if both points of the argument are granted as showing that these ideas are not totally derived from experience, it might be doubted whether they are enough to show that the ideas are innate. For might they not be grasped in some nonempirical manner at a later stage of life—for example, when (or if) someone comes to think in these very general terms? In Descartes's philosophy there is at least an implicit answer to this objection. Descartes thought that the pure ideas of mind and matter are used in the comprehension of experience even before they become conscious in reflection. It is by reference to these ideas that one forms the ordinary unreflective conceptions of oneself as having a series of thoughts or of a material object as enduring, occupying space, and having various characteristics, even though, before reflection, one's conceptions of these things will be confused. Thus, the operation of the pure idea is implicit in ordinary pre-reflective experience, and such experience begins to be acquired from the moment of birth; therefore, there is ground for calling the pure ideas innate.

In the case of God the argument is slightly different, since it is less clear that this idea is "put to use" in any pre-reflective way. Here Descartes may have meant to claim merely that it would be natural to the power and economy of God's operations that he should implant the idea of himself in the soul at its creation, "the mark," as Descartes put it, "of the workman on his work." There is indeed a difficulty in seeing how, for Descartes, there could be an idea in the mind of which the mind is not fully conscious (as this account implies), since for Descartes "mind" and "consciousness" were virtually equivalent. And this difficulty also arises for the ideas of mind and matter, since Descartes explicitly denied (presumably there was no alternative) that the infant or young person is fully conscious of his innate ideas; they are latent and emerge only later—in the process of learning language, for instance. Nevertheless, Descartes's claims for the operation of fundamental ideas in pre-reflective consciousness, although not quite consistent with his metaphysics of the mind, became an important element in later theories of innate ideas, especially in the debate with empiricism.

INNATE PRINCIPLES. Descartes appealed only to innate ideas, or concepts, the materials of judgments and beliefs. He did not invoke innate principles, or propositions, his view apparently being that granted innate ideas, we have only to grant in addition a certain power of the mind to elicit features implicit in these ideas in order to explain how necessary knowledge could be derived from innate ideas (as he supposed it could).

Leibniz, however, who continued the Cartesian insistence on innate ideas, added a requirement for innate principles. His argument was of the same general type as that ascribed to Descartes with respect to the ideas of mind and matter: If there were no innate and unlearned propositions, we could learn no propositions at all—at least not by way of logical deduction. For, he argued, confronted with any valid inference of the form " P , so Q ," we could not see that Q followed from P except by having already grasped the necessary truth of the proposition "if P then Q ." Thus, in order to follow any inference and to learn anything by deduction, first premises are required that must themselves be unlearned.

An objection to this argument can be seen from the famous difficulty raised by Charles L. Dodgson (Lewis Carroll) that if there is necessarily a difficulty in seeing the validity of the original inference as it stands, the same difficulty will recur with the inference obtained by the addition of the "innate" major premise; to grasp the validity of this inference, another major premise would seem to be required, and so on, thus starting a vicious regress. Dodgson's point makes it clear that no multiplication of premises can be adequate to extricate the validity of an inference; what is needed is something of a different category, a rule. At this point a characteristic empiricist rejoinder to Leibniz's puzzle is to claim that the rules of inference are not unlearned but are learned in the course of learning a language (they are the rules implicit in the correct use of "if," "then," "not," and so on). This illustrates the natural and perhaps inevitable tendency of empiricism, in contrast with rationalism, to turn to a linguistic account of logical necessity. (Such an account, however, even if adequate in itself, may not dispose of the issues as thoroughly as empiricism has tended to believe; the question remains of what is involved in learning a language.)

Leibniz, in introducing the argument just considered, explicitly stated that he was of the "Platonic" opinion that a priori knowledge (at least) is innate and "recollected" (*New Essays*, Book I). There is a difficulty, however, in knowing how far the doctrine is supposed to range: Leibniz's doctrine that the soul is a monad and

that every monad only develops its own inner potentialities, being unaffected by anything outside, implies that in one sense all thoughts, of whatever kind, are innate. This problem involves major questions in the interpretation of Leibniz—in particular, of his views on sense perception. However, it seems reasonable to say that at least in his remarks on innateness in the *New Essays* Leibniz was distinguishing between kinds of knowledge and ideas, such that some (the pure and a priori) can be said to be innate and others cannot.

Leibniz's remarks were in criticism of the First Book of John Locke's *Essay concerning Human Understanding*, and they constitute a subtle consideration of the issues lying between rationalism and empiricism at this point. Locke's First Book, although called "Of Innate Ideas," is in fact chiefly concerned with innate principles (and in some part with the alleged innate principles of morality that had been advanced by his adversary, Lord Herbert of Cherbury). Locke considered various characteristics supposed to show that a given proposition is innate (that it is universally believed, that it is assented to as soon as understood, and so forth), and had little difficulty in showing that these are inadequate. He then turned to the consideration that tiny children do not display elaborate conceptions of logic and mathematics such as are alleged by rationalists to be innate. His principle in this instance was "There is nothing in the mind of which the mind is not conscious"; if these conceptions were innate, they would be in the infant's mind, hence it would be conscious of them and (presumably) could display this consciousness. Leibniz, in reply, claimed that this so patently follows that Locke, in insisting on the principle about consciousness, was in effect begging the question: This principle is what the issue turns on. But, as has been seen, this was not how Descartes put the matter. Leibniz here made the cardinal point of the discussion his own non-Cartesian doctrine of subconscious perceptions (connected with his general doctrine of continuity).

DEBATE WITH EMPIRICISM. Once the obvious fact is granted that the allegedly innate ideas do not manifest themselves temporally before other experience, it may be wondered whether any point remains to calling them innate. It has sometimes been suggested that the doctrine of innate ideas merely depends on a confusion between a logical and a temporal sense of "prior." However, this is to underestimate the force of the rationalist claims that the allegedly innate material is such that its operation is a precondition of our learning anything else. It is not easy to decide how to evaluate these claims, as against the central empiricist claim that no such preexisting material

need be postulated (the so-called *tabula rasa* theory of the mind). For one thing, empiricism in its first developments tended to make up for the lack of original raw material by crediting the mind with a very elaborate set of operations. This was evidently the case with Locke, who used such notions as "abstraction," "reflection," and "intuition"; who spoke of "ideas" that are not evidently mere copies from sense perception; and who admitted a non-empirical notion of "substance" and its powers. His position retained a number of rationalist elements. The much more economical apparatus of David Hume, which in effect admits nothing but sensations, their copies, and the operations of association, defines a quite distinctive empiricist theory.

If the debate about innate ideas is cast in terms of a Humean empiricism, there remain principally two issues, one logical and one psychological. The logical issue concerns the question whether highly general concepts, such as those used in mathematics and the sciences, are reducible to or analyzable into those sorts of empirical concepts that can plausibly be said to be derived from sense experience. It would be widely agreed that the answer to this question would be "no." The second, psychological issue is whether the acquisition of concepts, such as occurs in language learning—and this would include even the supposedly straightforward empirical concepts—can be adequately explained by a psychological model postulating only the minimum empiricist requirements of sense perception, retention, association, and so forth. There is influential opinion (held by Noam Chomsky and others) that the answer to this, too, must be "no"; any adequate model may well require stringent innate constraints on the direction and nature of generalization from learning situations. How far these restraints might be supposed to approximate to the rationalists' conceptions of innate ideas—or, in other words, whether the model demands an innate analogue to the possession of concepts—remains to be seen.

If this is indeed an open question, then there is an explicitly psychological version of the rationalist view that is still worth serious consideration. This is not, of course, to say that the innate elements in an adequate model would be likely to correspond to the particular sorts of "ideas" that the rationalists selected for this status—such as the metaphysical notions of God, matter, and mind. Also, there was certainly an endemic confusion, in both the rationalist and the empiricist position on this issue, between psychological and logical issues. Nevertheless, there is still some life in the question, in both its logical and its psychological aspects, the occur-

rence of the psychological term *innate* in the original debate not being merely the result of confusion.

KNOWLEDGE

It was remarked above that there would now be wide agreement that many general theoretical concepts of mathematics and the sciences do not admit of total reduction to empirical concepts. In contrast with positivist or operationalist views it would be agreed by many that such concepts as “mass,” for instance, are not a mere shorthand for sets of possible observation data. Such agreement, however, although it would constitute a rejection of strict empiricism, would not in itself constitute an acceptance of rationalist views about such concepts. It is possible to think that these concepts “transcend,” or “go beyond,” the empirical merely in virtue of conventional elements—that they are parts of humanly constructed models of reality which relate the observable by imposing a structure on it.

Essential to rationalism, however, is a realistic view (incompatible with even a modified empiricism) about the relation of these concepts to reality and about the necessary relations obtaining between these concepts themselves. The intellectual grasp of these concepts and the truths involved in them is seen as an insight into an existing and unique structure of the world. It is not easy to express this picture (which in varying degrees dominated the rationalists) in less figurative language, but the picture has at least two consequences: that there is a unique set of concepts and a unique set of propositions employing these concepts that adequately express the nature of the world, and that these propositions form a system and could ideally be recognized as a set of necessary truths. There are, admittedly, difficulties about the last point, particularly with reference to Leibniz (these will be considered in the next section). However, something like this general picture is central to rationalism and leads immediately to the question of how anyone can come to know this uniquely correct representation of the world. This invites two more specific questions: What, in general, is the guarantee that knowledge of the world is possible? how can any individual tell in a particular case whether he has hit on some genuine piece of knowledge?

DESCARTES'S EPISTEMOLOGY. Most rationalists tended to answer the first of the above questions by referring to God; some, but not all, did the same for the second; and they varied in the priority that they assigned to the two questions. Descartes started famously with the second question and found the answer in the “clear and distinct

perceptions” of the intellect. Proving, as he supposed, the existence of God via clear and distinct perception, he then employed God’s perfection of “being no deceiver” to establish in general terms the reliability of beliefs that went beyond clear and distinct perception. He was, however, so impressed by the thought that it was only in virtue of humanity being created and sustained by God that he could know anything at all, that he was constantly tempted to double back and use the divine perfection to guarantee even the basic clear and distinct perceptions, thus laying himself open to the charge of arguing in a circle.

However this may be, it is notable that in Descartes “clear and distinct perception” is a thoroughly epistemological category. The truths that can be clearly and distinctly perceived do not constitute one homogeneous logical or metaphysical class of truths; the class includes at least statements of contingent existence (his own, in the *cogito*) and of necessary existence (that of God), contingent statements about immediate psychological experience, and necessary truths about the relations of ideas. The status of these last, which Descartes called eternal truths, is somewhat obscure. Descartes held, in the Augustinian-Scotist tradition, that they were the products of God’s will; but it is left unclear what it is that God has brought about in creating eternal truths, and hence what it is that one knows in knowing them.

THE CARTESIAN TRADITION. The development of the Cartesian tradition within rationalism tended to emphasize to an even greater extent the theological elements in Descartes’s theory of knowledge. Thus Nicolas Malebranche retained for the individual case the test of “clear and distinct perception” in a style that seems to assimilate it to moral perception and the promptings of conscience: “One should never give one’s complete assent except to propositions which seem so evidently true that one could not reject them without feeling an interior pain, and secret reproaches of the reason” (*De la recherche de la vérité*, I, Ch. 2; for the moral analogue, see Bossuet, *Traité de la connaissance de Dieu et de soi-même*, Ch. 1, Sec. 7).

Malebranche gives a strongly Augustinian and indeed Neoplatonist turn to the general account of God’s guarantee of the possibility of knowledge. His doctrine was that all our knowledge of the external world is mediated by God; the mind of God contains paradigm ideas in whose form he created the world, and it is these same ideas of which we are conscious when thinking about the world. This is the meaning of Malebranche’s saying that we see all things in God. This doctrine, apart from serving religious purposes, was also an attempt to get around

the difficulties inherent in Descartes's own causal account of relations between matter and mind (which will be considered more generally later in this entry).

The role of God in the foundations of knowledge takes different and less extreme forms in other areas of the rationalist tradition. The greatest contrast to the Malebranche development of Cartesianism might plausibly be said to be Spinoza's system. It is true that Spinoza did assert that it is the nature of God that guarantees the correspondence of our thoughts to the world, but he so transmuted the notion of God that the doctrine is only verbally similar to Cartesianism. "God" is one name ("Nature" is another) for the one substance, that is, everything that there is. This substance has infinitely many attributes, of which we can comprehend only two, mind and matter. These two attributes are necessarily parallel to one another, and corresponding to any mode of the one attribute there must be a mode of the other. Hence, thought and the material world are inherently adjusted to one another, and the development of knowledge consists in the project of rendering the thought component of this relation as clear (in Spinoza's term, as "active") as possible. It admittedly remains obscure how, within the constraints of Spinoza's determinism, this can be regarded as a "project" at all. Despite this and the other notorious difficulties, Spinoza's system is particularly interesting in the present connection as a thoroughgoing attempt to answer the crucial question that was left very much in the air in Descartes's thought, namely, how any knowledge of a necessary truth, regarded as knowledge of the relations of ideas, could also constitute knowledge of the world.

Leibniz's system, for all its radical differences from Spinoza's, resembles it in one respect having to do with the foundation of knowledge: The general possibility of the correspondence of thought to the world is guaranteed metaphysically by the existence of a correlation between the two. The monads are not affected by anything outside and each develops its own activity from within, but a correspondence between the activities of the monads is given by the "Prestablished Harmony"; and knowledge, the correspondence between "conscious" states of certain monads and other monads, is a special case of this. The Prestablished Harmony, however, depends on God's optimal choice, that is, on God's benevolence. Thus, in a less explicitly epistemological form, Leibniz (in contrast with Spinoza) reverted to the original Cartesian standpoint, in that there is a transcendent and personal God who has a will, and it is a result of his will that there is an ultimate guarantee of the possibility of knowledge.

In general, however, Leibniz was not much concerned with epistemological problems; in particular, he was uninterested in the question that was the starting point for Descartes: How can the individual be certain of the truth of anything? Spinoza was concerned with this question, and tried to develop a theory of knowledge that would avoid the regress latent in Descartes's method, arising from the question of how one knows that one knows. In Spinoza's "degrees of knowledge" it is an essential property of the highest, or intuitive, degree that it is self-guaranteeing. Even so, there is an evident shift in the Spinozistic outlook away from the Cartesian question "What do I know, and how do I know it?" Spinoza, like Leibniz and many other rationalists, gave the metaphysical description of the world from "outside," from a "God's-eye" standpoint rather than from the subjective epistemological standpoint from which Descartes (although unsuccessfully) tried to work. It is, perhaps, a mild irony of the history of philosophy that Descartes's attempt to start with subjective questions of epistemology and to "work out" from there had more influence on the development of empiricism than on later rationalism.

SCIENCE AND SCIENTIFIC METHOD

No attempt will be made here to give an account of the detailed developments of the philosophy of science within rationalist thought, or of the actual scientific conceptions held by or associated with rationalists, although these are of course of great importance, most notably in Leibniz's critique of Cartesian physics and in the development of his concept of force. We shall consider only one or two general points about the rationalists' conception of a completed science and associated notions of scientific method.

Rationalist developments in these matters can usefully be seen in the light of an unresolved conflict within Descartes's system between the method of approaching scientific inquiry and the expected shape of the final product. Descartes favored in principle an approach to inquiry that might be called systematically exploratory. This he called the analytic method; and the straightforward exposition of the results of such an inquiry would be heuristic in style, explaining the resolution of difficulties as they were encountered in the systematic progress. He seems, however, also to have had a picture of a completed science as a complete deductive system, ideally expressed in a unique system of theorems with necessary truths (of a metaphysical character) as its axioms; this he termed the synthetic method of exposition. There is, perhaps, no essential clash between these two ideas of

method and result; but Descartes seems not to have been clear about the relation between the two or how this specific method, fully pursued, would yield this specific result. Ambiguities about this question emerge in Descartes's accounts of the role of experiment, in which he sometimes gives the incoherent impression that he is both engaged in logical deduction of scientific laws from self-evident metaphysical premises and doing experiments to assist him in this deduction. On the whole, it is probably better to regard the idea of a complete formally deductive metaphysico-scientific system as less important in Descartes's thought than is sometimes supposed, and to see him as using certain limiting principles of scientific explanation, within which he constructs models to explain particular phenomena.

The idea of the total deductive system, however, had a powerful effect on rationalism and reached its most extreme expression in the work of Spinoza, where the "synthetic" method of Euclidean demonstration is explicitly regarded as necessary to the highest form of understanding. This was not just an expository preference; it was an expression of the basic Spinozistic outlook, which regarded the relation of cause to effect as that of logical ground to consequence—for Spinoza all explanatory relations were logical and timeless. The parallel orders of thought and matter, remarked on earlier, supposedly guarantee that the logical relations of ideas will constitute a totally adequate expression of the nature of the world. (A singular application of this notion of total parallelism is to be found in Ehrenfried Walter von Tschirnhaus, who in *Medicina Mentis* [1687] argued that an adequate definition of laughter should be able to produce laughter.)

Leibniz, partly under the influence of Erhard Weigel, was also attracted to the "geometrical method." He devoted a good deal of effort to the project of a universal calculus, which would enable arguments on any subject matter to be cast into a rigorous demonstrative form. However, the idea of such a calculus in no way presupposes an ideal of being able to demonstrate scientific truths from metaphysical or other supposedly self-evident axioms, which was the Spinozistic and, on occasion, the Cartesian ideal. Even if Leibniz started with the notion that it should be possible to settle any argument by appeal to the self-evident, he abandoned it in his mature philosophy, in which he made fundamental the distinction between "truths of reason," which can be established by logical insight on the basis of the law of noncontradiction, and "truths of fact," which depend on the principle of sufficient reason and cannot be established on logical grounds alone. There are some notori-

ous difficulties about this distinction, especially concerning the question of the nature of the contingency of "truths of fact," since Leibniz also held the further general principle that in all true propositions the predicate is contained in the subject. It does seem clear, however, that there is an ineliminable contingency about "truths of fact," and hence that the aspiration of reducing all knowledge to a system of deductions from self-evident premises must be impossible in the Leibnizian system.

Francis Bacon said in his *Cogitata et Visa* (1607), "Empiricists are like ants, they collect and put to use; but rationalists, like spiders, spin threads out of themselves." Bacon, of course, preferred the ants. Although there is some element of truth in the image of the spider, as applied to some rationalist thinkers, it does less than justice to the substantial empirical work done under rationalist inspiration. This is all the more so if one counts Galileo Galilei's view of science as fundamentally rationalist. He certainly rejected any kind of Baconian empiricism and shared the rationalist vision of a mathematical structure of reality that intellectual insight could grasp; but he perhaps had a more sophisticated feeling than any of the philosophers for the balance of imagination and experiment in physics. The rationalist tradition certainly embodied fundamental insights (lacking in empiricism) about the nature of science; above all, it saw the importance of mathematical structures in physical explanation and the vital possibility of a theory's making a conceptual jump beyond the observations and not merely (as in empiricism) an advance in generality. Its sense of the activity of the scientific mind, of its restructuring of observations through concepts and models, was very significant. At the same time, empiricism rightly fought for a clearer distinction between pure mathematics and natural science, undermined the aspirations to final certainty that dogged the rationalists, and emphasized the role of laborious observation and experiment in contrast with the rather dreamlike quality of rationalist visions of the universe. No clearer case exists in the history of philosophy of the need for, and eventual occurrence of, a synthesis; one aspect of that synthesis is neatly summed up in a remark of Giorgio de Santillana that "the true scientist has an empiricist conscience and a rationalist imagination."

SUBSTANCE AND CAUSALITY

In the history of classical empiricism the concepts of substance and of active causal power together became progressively weaker and were finally abandoned. Thus Locke employed the full Cartesian array of both material

and mental substances, both possessing causal power; George Berkeley banished material substance, partly on the ground that it could not be conceived of as possessing causal activity, which belongs only to mental substance; Hume maintained that the notions of substance and of causal activity are unintelligible. By contrast, in the rationalist tradition the notion of substance has not declined; developments in the idea of causal activity, although partly parallel to the idea of substance, are very different; in general the fortunes of “substance” and of “causal activity” have not been directly linked, as they have proved to be in empiricism—both have undergone considerable and partly independent variations.

In the case of substance (which will be very briefly considered here) the concept has not so much been criticized as used in differing ways to express differing metaphysical views of the world. On one measure, at least, the extremes in this respect are represented by the philosophies of Spinoza and Leibniz. Spinoza gave what he claimed was an a priori demonstration that there could be only one substance (*Deus sive Natura*, God or Nature); this was intrinsically neither material nor mental, these distinctions arising (as noted above) only at the level of the different attributes of this same substance. Essential to Leibniz’s outlook, on the other hand, was an infinite set of substances, the monads, each of them different from all the others. In their character, although there are difficulties of interpretation on this point, they are more of a mental than of a material kind.

On the question of causality an important stream in the history of rationalism stems from the problem left by Descartes, concerning the causal interaction of mind and matter. Descartes’s own view, which postulated simple efficient causation as holding between the two types of substance, failed to appeal to even the most ardent Cartesians, and their attention was particularly directed to this question, although difficulties about the meaning of causation even between material bodies also were considered. The natural tendency in the Cartesian tradition was to move toward attributing all causal power to God, and this movement of thought culminated in the doctrine of occasionalism—that both physical and mental events in the world are occasions for the application of God’s power, which itself directly produces what would normally be called the effects of those events. This doctrine is most thoroughly expressed in the writings of Malebranche. Similar views, however, are to be found in Louis de la Forge (*Le traité de l’esprit et de l’homme*, 1666) and Géraud de Cordemoy (*Le discernement du corps et de l’âme*, 1666), whose work was known to Malebranche.

The theory of occasionalism can be usefully contrasted with Berkeley’s empiricist account of causation. For both the only genuine activity was spiritual. For Berkeley the effects of such activity were also spiritual (mind can affect only mind), and indeed there was no other type of substance. The occasionalists retained material substance and did not find it unintelligible that mind can act upon matter; however, they held that the only mind for which such action is intelligible is the infinite mind of God. Here, as elsewhere, the questions of the gulf between mind and matter and of causation as activity emerge as of common concern to both rationalist and empiricist metaphysics, the influence of Descartes being clearly discernible in both.

Another writer who inclined to occasionalism was Arnold Geulincx (*Ethics*, 1665; 2nd ed., 1675); however, he also suggested a different model for causality, in which God did not, as in occasionalism, make a constant series of miraculous interventions into the natural order but had established ab initio a series of coordinated developments, the relations between which are what is taken for causal interaction. In this connection Geulincx introduced the example of the two clocks, perfectly adjusted to keep the same time, one of which strikes when the other shows the hour; the appearance of causal connection between them is only a result of precise prearrangement.

This same analogy was frequently employed by Leibniz in explaining his own very thoroughgoing version of this thesis, in which all appearance of causal interaction is an instance of the preestablished harmony between the several developments of the monads. Here again there is a notable contrast with and a similarity to empiricism: Both Leibniz and Hume, each representing the culmination of one of the two traditions in its classical form, deny the existence of “transeunt action” between different things and see what is called causation as a correlation between phenomena. Leibniz, however, emphasized some kind of spontaneous activity within the monad, while for Hume neither such activity, nor any notion of a substance, such as a monad, was acceptable. The views of these two philosophers are also worthy of comparison on other subjects, such as space and time; and the points of contact between them are the more significant in the light of the radical and very obvious differences in the spirit, method, and presuppositions of their two philosophies. These differences in the two culminating figures constitute a paradigm, almost a caricature, of the divergent styles of thought associated with rationalism and empiricism, while at the same time similar pressures in the his-

tory of thought produced partly parallel developments in each.

RATIONALISM IN ETHICS (PRACTICAL-REASON APPROACHES)

Practical-reasoning theory is a kind of metaethical view—alongside noncognitivism and other cognitivism such as naturalism and rational intuitionism—that aims to understand ethics as rooted in practical reason.

Tradition divides the faculty of reason into two parts: theoretical and practical. Theoretical reason concerns what we should believe, practical reason what we should do. Beliefs aim to represent reality and are mistaken or in error when they do not. Theoretical reason's task, therefore, is to discover what is true of the independent order of fact to which belief is answerable. But what about practical reason? What could make it the case that an action is something a person ought to do?

Plainly, ethical convictions also aim at a kind of objectivity. If Jones thinks he should devote all his resources to conspicuous consumption but Smith thinks that Jones should donate some to help the poor, their convictions conflict. Only one, at most, can be true.

Practical-reasoning theories aim to explain the objective purport of ethical conviction, but in a way that respects a fundamental distinction between theoretical and practical reason. Like noncognitivism, these theories sharply distinguish between ethics and those theoretical disciplines that aim to represent some independent reality, whether the order of nature or some supersensible metaphysical realm. They therefore reject both naturalism and rational intuitionism. But they also deny noncognitivism, since they hold that ethical propositions can be true or false.

According to practical-reasoning theories, objectivity consists not in accurate representation of an independent order, but in demands that are universally imposed within an agent's own practical reasoning. What marks ethics off from science is its intrinsically practical character, its hold on us as agents. It is because there is such a thing as practical reason, a form rational agents' deliberations must take, that there is such a thing as ethics.

But what form does rational deliberation take? Uncontroversially, practical reasoning includes reasoning from ends to means. The interesting debates concern what else it involves, if anything, and how instrumental reasoning is itself to be understood. Humeans maintain that means-end reasoning exhausts practical reason and that instrumental reason can be reduced to the use of theoretical reason in discovering means to ends. They tend not to be practical-reasoning theorists, however, since they argue that ethics fundamentally concerns what engages human sympathy or moral sentiment rather than what it is rational for a person to do. By contrast, practical-reasoning theorists deny that practical reason can be reduced to theoretical reason. As Christine Korsgaard has argued, even instrumental practical reason directs an agent who has already used theoretical reason in determining that *B* is the only means to his end *A* to undertake *B* (or to give up *A* as an end). In this way instrumental practical reasoning parallels the structure of *modus ponens* in theoretical reasoning (the move from "*p*" and "if *p*, then *q*" to "*q*").

Pursuing the analogy with theoretical reasoning (while insisting on irreducibility) further suggests that instrumental reasoning cannot exhaust practical reason. When we reason from our beliefs—for example, with *modus ponens*—we reason from their contents, not from the fact of our believing them. We reason from *p* and if *p*, then *q*, not from the facts that we believe that *p* and that we believe that if *p*, then *q*. Similarly, when we adopt an end, we do not simply select it by sheer fiat. Rather, we choose it as something (we think) there is some reason to

do. Thus, when we reason from our ends, we do not reason from the fact that they are our ends but from our commitments to them as things it makes sense to do. That is why instrumental rationality is so uncontroversial. As R. M. Hare argued, it is questionable at best that it follows from the facts that a person's end is to kill someone in the most grisly possible way and that using a cleaver is such a way that the person ought, or has some normative reason, to use a cleaver. What is uncontroversial is simply that the support of reasons transfers from end to means, other things being equal, and from not taking the (only available) means to renouncing the end, other things being equal. It follows only that a person ought to use a cleaver or give up my end.

On grounds such as these, practical-reasoning theorists tend to hold that instrumental rationality cannot exhaust practical reason. But how are we to deliberate about ends? What makes something a reason for adopting an end? Since they hold that reasons for action are necessarily connected to the agent's deliberative perspective, practical-reasoning theorists generally adopt what Korsgaard has called the internalism requirement, according to which a reason must be something the agent could, in principle, be moved by in deliberation and act on. This makes it a necessary condition of something's being a reason for an agent that she would be moved by it insofar as she deliberated rationally.

But what then is rational deliberation? Practical-reasoning theorists are loath to derive a deliberative ideal by independently specifying paradigm reasons for acting and holding that deliberation is rational when it responds appropriately to them. That would theorize practical reason too much on the model of theoretical reason. Rather, they maintain that rational deliberation must be understood formally, so that reason for acting is a status consideration inherit when it is such that it would move an agent who formed her will in accordance with that deliberative ideal.

The aspects that have been considered so far are relatively common among practical-reasoning theories, although not, perhaps, universal. Within these theories, however, there is a major division between neo-Hobbesians and neo-Kantians. Although nothing on the surface of practical-reasoning theory might suggest this result, it is notable that both camps attempt to vindicate the commonsense idea that moral obligations are supremely authoritative. Both argue that (at least some central) moral demands are demands of practical reason.

NEO-HOBBSIANISM

Recent versions of this view have their roots in ideas advanced by Kurt Baier in the late 1950s and attempt to address a significant problem faced by Baier's early view. Baier argued that reasons for acting must ultimately connect with the agent's interests. This does not reduce all practical reasoning to prudential reasoning, since other forms may advance agents' interests also. Specifically, Baier argued that morality may be viewed as a system of practical reasoning that is in the interest of everyone alike. Since it is mutually advantageous for everyone to regard moral obligations as supremely authoritative, Baier concluded that they actually do create overriding reasons for acting.

David Gauthier objected to Baier's theory that, while it is in the interest of each that all regard interest-trumping moral reasons as supreme, it is unclear how this can show that an individual agent should so regard them, since it will still most advance her interest to act prudentially when morality conflicts with self-interest. Why, then, might it not be true that instrumental and prudential reasoning exhaust practical reason, even if a person should hope to live in a world in which other people view things differently and (mistakenly) treat moral reasons as authoritative?

Gauthier is himself responsible for the major recent neo-Hobbesian practical-reasoning theory. Like Baier, Gauthier begins from the premise that practical reasoning must work to advance the agent's interests, although here his account is more nearly "internalist," since he understands a person's interests to consist in what she would herself prefer were she to be fully informed. Also like Baier, Gauthier argues that the fact that mutual advantage may require individuals to constrain their pursuit of self-interest can be used to show that practical reason counsels this constraint. However, it is not enough that it be true that everyone would do better if everyone so constrained his or her prudential reasoning. The crucial point for Gauthier is that individuals can do better if they constrain self-interest by a willingness to abide by mutually advantageous agreements.

Two agents who appear to each other to be unconstrained pursuers of self-interest simply cannot make agreements, however mutually advantageous the agreements might be, if these agreements would require the agents to act contrary to their own interests. In what have come to be known as prisoner's dilemma situations, therefore, mutually advantageous rational agreement between such persons is impossible. If each believes the other will rationally defect from the agreement on the

condition that doing so is in her interest, then neither can rationally make the agreement.

Personal advantage therefore counsels presenting oneself to others as someone who is not an unconstrained maximizer of self-interest. Of course, it is possible, theoretically, for someone to do this while still deliberating as an unconstrained prudential reasoner. But it may not be practically possible, Gauthier argues, at least not for normal human beings. Human motivation may be sufficiently translucent—through involuntary response, for example—so that the least costly way of appearing to others as someone who can be relied upon to keep mutually advantageous, interest-constraining agreements is actually to be such a person. If that is so, then instrumental and prudential reason will not support themselves as principles to guide rational deliberation. On the contrary, they will recommend that agents deliberate in terms of an alternative conception of practical reason that counsels keeping mutually advantageous agreements, even when this is contrary to self-interest.

As a practical-reasoning theorist, Gauthier believes that reasons for acting cannot be understood except in relation to what should guide a rational agent in deliberation. And he believes that a rational agent is someone whose dispositions of choice and deliberation serve her best and most advance her interest. But just as indirect forms of ethical consequentialism, such as character- and rule-consequentialism, face the objection that they are unstable and threaten to collapse into either act-consequentialism or deontology, Gauthier's indirect consequentialist theory of rationality may face the same objection. What motivates the move away from unconstrained prudence, on the grounds that it cannot support itself in the agent's practical thinking, is a view about the role a principle of rational conduct must be able to play in the deliberations of an autonomous rational agent that may be more Kantian than Hobbesian in inspiration.

NEO-KANTIANISM

This contemporary tradition may be held to date from Thomas Nagel's *The Possibility of Altruism* (1970) and John Rawls's reinvigoration of Kantian moral and political philosophy in *A Theory of Justice* (1971) and "Kantian Constructivism in Moral Theory" (1980). Nagel's book was read as having both a modest and a more ambitious agenda. His more modest goal, suggested by his title, was to show how such "objective" (or, as he later termed them, "agent-neutral") considerations as "that acting would be relative *someone's* pain" can be genuine reasons for acting. A consideration can be rationally motivating, he argued,

even if the agent lacks any relevant desire for acting on it other than one that is motivated by the awareness of that very consideration. A person may be moved, for instance, by considering long-term interests. And if motivation at a distance is possible with prudence, it can happen with altruism as well. Altruistic and other agent-neutral considerations can be rationally motivating.

Nagel's more ambitious agenda was to argue that practical reasoning is subject to a formal constraint that effectively requires that any genuine reason for acting be agent-neutral. Stressing the "motivational content" of genuine practical judgments, Nagel argued that avoiding a kind of solipsism is possible only if an agent is able to make the same practical judgment of himself from an impersonal standpoint as he does from an egocentric point of view. Since accepting practical judgments from one's own point of view normally motivates, Nagel maintained, making the same judgment of oneself from an impersonal standpoint should normally motivate also. But this will be so only if the reasons for acting that ground practical judgments are agent-neutral. So it is a necessary condition for avoiding practical solipsism that agents take considerations such as that something will advance their own ends or interests as reasons only if they regard them as instantiating more general, agent-neutral reasons, such as that acting will advance someone's ends or interests. Nagel later retreated from this strong claim in a direction that is arguably even more Kantian. Autonomous agency, he later argued, involves an agent's acting on reasons she can endorse from an objective standpoint, and such a set of reasons will include both agent-relative and agent-neutral ones.

Neo-Kantian practical-reasoning theories have been put forward by a number of philosophers, including Alan Gewirth, Stephen Darwall, and Christine Korsgaard. Korsgaard's sympathetic reconstruction of Immanuel Kant's own arguments in a series of papers has been especially influential. Common to all these neo-Kantian approaches has been the idea that the practical reasoning of an autonomous agent has a formal structure, with its own internal standards and constraints, and that these provide the fundamental truth and objectivity conditions for ethical thought and discourse. Thus, Gewirth maintains that fundamental moral principles are derivable from propositions to which a rational agent is committed from within the deliberative standpoint in acting. And Korsgaard argues that even instrumental theorists are committed to the "hypothetical imperative" as a practical norm. Since, however, we regard ourselves to be free as agents to adopt and renounce ends, practical reason can-

not possibly be exhausted by any mere consistency constraint, such as the hypothetical imperative. It follows, the neo-Kantians argue, that practical reason requires norms to regulate the choice of ends no less than to guide the choice of means. In choosing ends for reasons we commit ourselves implicitly to principles of choice as valid for all. But such a commitment is not, they claim, a hypothesis about some independently existing order of normative fact to which we might have cognitive access. That, after all, is precisely the difference between theoretical and practical reason. So the standards to which deliberation is subject must ultimately be based on some formal principle of impartial endorsement that is internal to free practical reasoning itself. And this will be so, they conclude, only if practical reasoning is regulated by some such principle as the categorical imperative, which requires that one act only on principles that one can will to regulate the deliberation and choices of all. If moral demands are ultimately grounded in the categorical imperative also, it will follow that moral demands are demands of practical reason.

Stephen Darwall (1996)

RATIONALISM IN ETHICS [ADDENDUM]

Moral rationalism, like many philosophical “isms,” is an umbrella term for a variety of constituent claims. Not all moral rationalists endorse all of these claims, but the central ones that have been associated with moral rationalism are:

- 1) The metaphysical thesis: Basic moral requirements are constituted by the deliverances of sound practical reason.
- 2) The epistemological thesis: Humankind’s basic moral requirements are knowable a priori.
- 3) The normative thesis: Moral requirements entail excellent reasons for action.

The metaphysical thesis is at the heart of practical reason approaches to ethics, such as those of Thomas Hobbes and Immanuel Kant, and, in modern times, David Gauthier, Christine Korsgaard, and Michael Smith. Though the views of these thinkers differ in many important respects, they agree that our basic moral duties are a function of sound practical reason. This means that something is a moral duty for a person just because it would be regarded as rationally authoritative were that person (or some idealized counterpart thereof) to reason soundly from his or her most important commitments.

What distinguishes adherents of the metaphysical thesis from one another are their views about the nature of our fundamental commitments, and about what sound practical reasoning looks like. Kantians, such as Korsgaard, will consider some of our fundamental commitments as intrinsic to human nature, and so shared by all human moral agents. Successful reasoning on this shared basis will yield a set of universal moral duties. Hobbesians, such as Gauthier, deny that humans have any essential or intrinsic ends. Yet Gauthier believes that sound reasoning—which, for him (unlike Kantians), is restricted to instrumental reasoning designed to maximize self-interest—will also yield a set of common moral duties. This is because each of us is likeliest to do the best by adhering to (and acquiring a disposition to conscientiously adhere to) mutually beneficial rules that sometimes mandate self-sacrifice, and these are just what Gauthier thinks moral rules are.

Smith’s view is a kind of ideal observer theory. What we have reason to do is a matter of what an ideal adviser would want us to do. This ideal advisor shares our fundamental desires, but is fully factually informed, has flawless

reasoning abilities, and is possessed of a fully coherent set of desires. Though such advisers obviously do not really exist, they play a crucial role in determining the content of our moral duties. Smith endorses the Kantian tenet that sound reasoning is more than self-interested instrumental reasoning. He endorses the Humean view that all of our fundamental commitments are contingent. But he believes that sound reasoning on the basis of disparate commitments will nevertheless yield a universal set of rationally authoritative moral requirements: The ideal advisers would converge in all of their basic recommendations.

What all of these thinkers share is a belief that the content of our basic moral duties conceptually depends very importantly on the outcome of sound practical reasoning. Perhaps the nature of this dependence can best be seen by contrasting their metaphysical thesis with that of moral realism. Moral realists, some of whom consider themselves rationalists because of their endorsement of the epistemological and normative theses, nevertheless deny the metaphysical thesis. Whichever picture of the ideal reasoner and the ideal reasoning process we adopt, the metaphysical thesis tells us that something is our moral duty just because a process of sound reasoning would ratify it. Moral realists, by contrast, might allow for the possibility of inerrant reasoners who infallibly identify all moral duties, but realists will insist that the content of our duties is fixed in a way that does not depend on the outcomes of such reasoning. Ideal reasoners will discover the moral truths there are to be discovered, rather than creating, through the exercise of sound practical reasoning, the content of our basic moral duties.

Though moral realists and those who endorse practical reason approaches to ethics are divided in their opinion of the metaphysical thesis, those among them who accept the rationalist moniker may still agree on the epistemological thesis. Moral rationalists in this domain believe that at least some moral knowledge is a priori. While experience may be needed to obtain an understanding of moral concepts, and empirical premises might be needed to determine what our all-things-considered duty in a given case might be, knowledge of fundamental moral principles can be had without relying on contingent, empirical premises for evidential support. Rationalists here believe, for instance, that one needs nothing other than a sound understanding of the proposition to be justified in thinking that, *prima facie*, it is immoral to rape or torture people solely for personal enjoyment.

Both moral realists and adherents of practical reason approaches to ethics are divided on the availability of a

priori moral knowledge. Among moral realists, the sides are drawn by reference to whether the emerging view takes the form of ethical naturalism or ethical nonnaturalism. Naturalists will see all knowledge, and so all moral knowledge, as a posteriori, available only by applying the same methods of discovery and justification as are utilized in the natural sciences. Ethical nonnaturalists, by contrast, will reject the attempted assimilation of ethics to natural science, and so will leave room for the possibility of a priori moral knowledge. Indeed, the historically most prominent moral realists, up to and including the British intuitionists of the early twentieth century (Henry Sidgwick, G. E. Moore, and W. D. Ross), all endorsed the idea that fundamental moral principles were self-evident: knowable solely on the basis of adequately understanding the content of the relevant principle. Robert Audi, the contemporary philosopher who has done most to develop this view, agrees with his historical forbears in attributing to reason the power to discern certain fundamental truths about reality—in this case, moral reality.

Like moral realists, adherents of practical reason approaches to ethics (and so of the rationalists' metaphysical thesis) disagree among themselves about the tenability of a priori moral knowledge. Kantians, who have championed the possibility of synthetic a priori knowledge in other areas, likewise endorse its possibility in ethics. But others, such as Gauthier, are avowed naturalists who believe that knowledge of an agent's moral duties depends crucially on knowledge of her contingent, fundamental commitments, and so cannot be a priori.

The normative thesis, which states that moral requirements entail excellent reasons for action, is accepted by all practical reason approaches to ethics. Indeed, a major attraction of such theories is that they are able to explain the intimate connection that might obtain between one's moral duty and one's reasons for action. We will always have reason to do as morality says, because morality is constructed from our own deepest commitments. If moral duties are rational extensions of our fundamental commitments, then, to the extent that we are rational, we cannot be alienated from what morality requires of us.

Moral realists have had a more difficult time explaining the reason-giving power of morality. Indeed, some, such as Peter Railton and David Brink, have given up on the idea that there is any necessary connection between moral demands and reasons for action. Such thinkers believe that something qualifies as a practical reason only if it furthers an agent's ends (all of which, in their view, are contingent). They believe that moral demands may

fail to serve an agent's ends. It follows that there may be no good reason to abide by the demands of morality.

If one retains this popular view of reasons, then the moral rationalist's normative thesis can be sustained in only one of two ways. The first involves rejecting moral realism, and taking up a practical reason approach that identifies our moral duties with the rational extensions of our commitments. Here, both our reasons and our moral duties will rely on these commitments, and this can explain the perfect alignment of morality and reasons for action. The second, more controversial way of defending both rational egoism and the normativity thesis, is to accept moral realism, and then to insist that fulfillment of our moral duties will always, of necessity, further our ends. Plato argued this way, and some theists who are moral realists do so as well. This is the less traveled path, however, because its defense requires that we posit a set of objective human ends that are invariably furthered by moral conduct. Such ends might be renounced by apparently coherent and rational individuals, and this has led to a great deal of suspicion about their existence.

The more common strategy for moral realists who want to vindicate the normativity thesis is to reject the view that reasons for action must always further the agent's ends. A misanthrope, for instance, might be morally bound to rescue another, if he can do so at little or no inconvenience to himself. According to the normativity thesis, there is therefore excellent reason for him to do so, even if none of the misanthrope's ends are furthered as a result. Given who the person is, he will reject the existence of such a reason. It will seem to the misanthrope an alien demand, of only spurious rational authority. It will play no role in explaining the actions he undertakes. Still, says the realist who embraces the normativity thesis, the misanthrope's reactions in such a case do not immunize him either from the moral duty, or from the practical reason that he ignores in his neglect of the victim he might have aided.

An adherent of the practical reason approach to ethics will insist that reasons be able to engage agents who are reasoning well from their fundamental commitments. And realists cannot secure this guarantee, since they do not make the content of moral demands dependent on the outcomes of sound practical reasoning. Realists will either concede the point, as Railton and Brink do, or affirm their allegiance to the normative thesis. In the latter case, they will deny that morality must engage all who are able to reason efficiently about securing their ends. The plausibility of such a denial is the subject of much contemporary metaethical discussion.

RATIONALITY

Philosophers have, at least characteristically, aspired to possess “rationality” but have not thereby sought exactly the same thing. Portrayed vaguely, rationality is reasonableness, but not all philosophers take rationality as dependent on reasons; nor do all philosophers have a common understanding of reasons or of reasonableness. Some theorists consider rationality to obtain in cases that lack countervailing reasons against what has rationality; they thus countenance rationality as, in effect, a default status. In ordinary parlance, persons can have rationality; so, too, can beliefs, desires, intentions, and actions, among other things. The rationality appropriate to action is practical, whereas that characteristic of beliefs is, in the language of some philosophers, theoretical.

Many philosophers deem rationality as instrumental, as goal oriented. You have rationality, according to some of these philosophers, in virtue of doing your best, or at least doing what you appropriately think adequate, to achieve your goals. If ultimate goals are not themselves subject to assessments of rationality, then rationality is purely instrumental, in a manner associated with David Hume’s position. Rationality, according to this view, is a minister without portfolio; it does not require any particular substantive goals of its own but consists rather in the proper pursuit of one’s ultimate goals, whatever those goals happen to be. Many decision-theoretic and eco-

nomical approaches to rationality are purely instrumentalist. If, however, ultimate goals are susceptible to rational assessment, as an Aristotelian tradition and a Kantian tradition maintain, then rationality is not purely instrumental. The latter two traditions regard certain rather specific (kinds of) goals, such as human well-being, as essential to rationality. Their substantialist approach to rationality lost considerable influence, however, with the rise of modern decision theory.

When relevant goals concern the acquisition of truth and the avoidance of falsehood, so-called epistemic rationality is at issue. Otherwise, some species of nonepistemic rationality is under consideration. One might individuate species of nonepistemic rationality by the kind of goal at hand; moral, prudential, political, economic, aesthetic, or some other. Some philosophers have invoked rationality “all things considered” to resolve conflicts arising from competing desires or species of rationality; even so, there are various approaches to rationality “all things considered” in circulation. The standards of rationality are not uniformly epistemic, then, but epistemic rationality can play a role even in what some call nonepistemic rationality. Regarding economic rationality, for instance, a person seeking such rationality will, at least under ordinary conditions, aspire to epistemically rational beliefs concerning what will achieve the relevant economic goals. Similar points apply to other species of nonepistemic rationality. A comprehensive account of rationality will characterize epistemic and nonepistemic rationality, as well as corresponding kinds of irrationality (e.g., weakness of will).

Taking rationality as deontological, some philosophers characterize rationality in terms of what is rationally obligatory and what is merely rationally permissible. If an action, for instance, is rationally obligatory, then one’s failing to perform it will be irrational. Other philosophers opt for a nondeontological evaluative conception of rationality that concerns what is good (but not necessarily obligatory) from a certain evaluative standpoint. Some of the latter philosophers worry that, if beliefs and intentions are not voluntary, then they cannot be obligatory. Still other philosophers understand rationality in terms of what is praiseworthy, rather than blameworthy, from a certain evaluative standpoint. The familiar distinction between obligation, goodness, and praiseworthiness thus underlies three very general approaches to rationality.

Following Henry Sidgwick, William Frankena has distinguished four conceptions of rationality: (1) an egoistic conception implying that it is rational for one to be

or do something if and only if this is conducive to one's own greatest happiness (e.g., one's own greatest pleasure or desire satisfaction); (2) a perfectionist conception entailing that it is rational for one to be or do something if and only if this is a means to or a part of one's moral or nonmoral perfection; (3) a utilitarian conception implying that it is rational for one to be or do something if and only if this is conducive to the greatest general good or welfare; and (4) an intuitionist conception implying that it is rational for one to be or do something if and only if this conforms to self-evident truths, intuited by reason, concerning what is appropriate. The history of philosophy represents, not only these conceptions of rationality, but also modified conceptions adding further necessary or sufficient conditions to one of (1)–(4).

Given an egoistic conception of rationality, one's being rational will allow for one's being immoral, if morality requires that one not give primacy to oneself over other people. Rationality and morality can then conflict. Such conflict is less obvious on a utilitarian conception of rationality. In fact, if morality is itself utilitarian in the way specified (as many philosophers hold), a utilitarian conception of rationality will disallow rational immorality. A perfectionist conception of rationality will preclude rational immorality only if the relevant perfection must be moral rather than nonmoral; achieving nonmoral perfection will, of course, not guarantee morality. As for an intuitionist conception of rationality, if the relevant self-evident truths do not concern what is morally appropriate, then rational immorality will be possible. An intuitionist conception will bar conflict between rationality and morality only if it requires conformity to all the self-evident truths about what is morally appropriate that are relevant to a situation or person. So, whether rationality and morality can conflict will depend, naturally enough, on the exact requirements of the conception of rationality at issue.

Richard Brandt has suggested that talk of what it would be rational to do functions to guide action by both recommending action and by making a normative claim that evaluates the available action relative to a standard. An important issue concerns what kind of strategy of using information to choose actions will enable one to achieve relevant goals as effectively as any other available strategy. Brandt has offered a distinctive constraint on such a strategy: A rational decision maker's preferences must be able to survive their being subjected to repeated vivid reflection on all relevant facts, including facts of logic. This constraint suggests what may be called (5) a relevant-information conception of rationality: Rational-

ity is a matter of what would survive scrutiny by all relevant information.

A relevant-information conception of rationality depends, first, on a clear account of precisely when information is relevant and, second, on an account of why obviously irrational desires cannot survive scrutiny by all relevant information. Evidently, one could have a desire caused by obviously false beliefs arising just from wishful thinking, and this desire could survive a process of scrutiny by all relevant information where the underlying false beliefs are corrected. In any case, a relevant-information conception of rationality will preclude rational immorality only if it demands conformity to all relevant moral information.

The egoistic, perfectionist, utilitarian, and relevant-information conceptions of rationality are nonevidential in that they do not require one's having evidence that something is conducive to self-satisfaction, perfection, general welfare, or support from all relevant information. Many philosophers would thus fault those conceptions as insufficiently sensitive to the role of relevant evidence in rationality. If relevant evidence concerns epistemic rationality, we again see the apparent bearing of epistemic rationality on rationality in general. The latter bearing deserves more attention in contemporary work on nonepistemic rationality.

Philosophers currently divide over internalism and externalism about rationality. If rationality demands reasons of some sort or other, the dispute concerns two senses of talk of a person's having a reason to perform an action. An internalist construal of this talk implies that the person has some motive that will be advanced by the action. An externalist construal, in contrast, does not require that the person have a motive to be advanced by the action. Bernard Williams, among others, has suggested that any genuine reason for one's action must contribute to an explanation of one's action and that such a contribution to explanation must be a motivation for the action. He concludes that externalism about rationality is false, on the ground that external reasons do not contribute to explanation of action in the required manner. Externalism about rationality does allow that reasons fail to motivate, but this, according to externalists, is no defect whatever. Externalists distinguish between merely motivating reasons and justifying reasons, contending that only the latter are appropriate to rationality understood normatively; what is merely motivating in one's psychological set, in any case, need not be justifying. Perhaps, then, disputes between internalists and externalists

will benefit from attention to the distinction between justifying and merely motivating reasons.

Modern decision theory assumes that, in satisfying certain consistency and completeness requirements, a person's preferences toward the possible outcomes of available actions will determine, at least in part, what actions are rational for that person by determining the personal utility of outcomes of those actions. In rational decision making under certainty one definitely knows the outcomes of available actions. In decision making under risk one can assign only various definite probabilities less than 1 to the outcomes of available actions. (Bayesians assume that the relevant probabilities are subjective in that they are determined by a decision maker's beliefs.) In decision making under uncertainty one lacks information about relevant states of the world and hence cannot assign even definite probabilities to the outcomes of available actions. Acknowledging that rationality is purely instrumental (and thus that even Adolf Hitler's Nazi objectives are not necessarily rationally flawed), Herbert Simon has faulted modern decision theory on the ground that humans rarely have available the facts, consistent preferences, and reasoning power required by standard decision theory. He contends that human rationality is "bounded" in that it does not require utility maximization or even consistency. Rather, it requires the application of a certain range of personal values (or preferences) to resolve fairly specific problems one faces, in a way that is satisfactory, rather than optimal, for one. Simon thus relies on actual human limitations to constrain his account of rationality.

Contemporary theorists divide over the significance of human psychological limitations for an account of rationality. The controversy turns on how idealized principles for rationality should be. This raises the important issue of what exactly makes some principles of rationality true and others false. If principles of rationality are not just stipulative definitions, this issue merits more attention from philosophers than it has received. Neglect of this metaphilosophical issue leaves the theory of rationality as a subject of ongoing philosophical controversy.

RAVAISSON-MOLLIEN, JEAN GASPARD FÉLIX (1813–1900)

The French spiritualist philosopher and art historian Jean Gaspard Félix Ravaisson-Mollien was born in Namur, Belgium. He received his philosophical training in Munich under Friedrich von Schelling and took a degree

in Paris in 1838 under Victor Cousin. His philosophical work began with his prize essay, *Essai sur la métaphysique d'Aristote*, and a short teaching career at Rennes in 1838. In 1840 he was appointed inspector general of libraries, a post that he held until 1860, when he became inspector general in the department of higher education. Meanwhile, as a semiprofessional painter he had become interested in classical antiquities, and in 1870 he was made curator in the department of antiquities in the Louvre. The fruit of this was his well-known set of reconstructions of the Venus de Milo.

The most influential of Ravaisson's publications was his *Rapport sur la philosophie en France au XIX^e siècle*, made at the request of the imperial government in 1867. At this time the school of Cousin was in the ascendancy in France, and it was difficult, indeed practically impossible, for a man who was not an eclectic to get an appointment in the university system. Ravaisson's purpose in his report was to show that there was a continuity in the French philosophical tradition and that French philosophers had always presupposed metaphysical principles that implied what he called spiritualism. This tradition, he maintained, always swung between sensationalism, phenomenalism, and materialism, on the one hand, and idealism, on the other. But spiritualism really began in the nineteenth century with Maine de Biran, who used as his starting point the human will and who held that the will is independent both of sensations and of ideas. This viewpoint, Ravaisson argued, was not only the proper beginning of a philosophy but also the only one that could unify the opposing tendencies of empiricism and idealism.

Such a conclusion was in clear contradiction to the tenets of Cousin's eclecticism, which aspired to fuse "the best in each philosopher." Ravaisson tried to show that such a fusion in reality consists in refuting those philosophies which displease the eclectic and retaining those which please him. In classifying all philosophies under the headings of sensualism, idealism, mysticism, and skepticism, Cousin accepted only that philosophy which he called idealism but which, said Ravaisson, was really a simple mixture of the Scottish philosophy of common sense with a few ideas from Maine de Biran. The eclectics, moreover, failed to understand these ideas. Ravaisson claimed for himself the credit of introducing the true thought of Maine de Biran to his contemporaries. Readers of this report were thus informed that the de facto official philosophy of the French universities was not only a foreign importation but also untrue.

Ravaisson was not satisfied with undermining eclecticism. He also felt it important to point out the weaknesses of positivism. These weaknesses, he claimed, arose from the identification of philosophical method with the methods of science. Science, which admittedly studies the external world, can never tell us anything about the internal world of thoughts, aspirations, desires, and dreams; and when it attempts to do so, it transforms them into quasi-external objects. This inevitably leads to materialism, for the laws of matter are the only laws that science can formulate. Science's basic categories are space and quantity, and its basic method is analysis. But the phenomena of consciousness are never spatial or quantitative, and to attempt to categorize them in these terms is to change their essential nature.

Ravaisson's report reviewed all the contemporary schools of thought and all the contemporary philosophers. It was a model of patience and thorough investigation and has become the primary source of information about individuals who are obscure and in some cases forgotten. It did not stop at professional philosophers but looked into the presuppositions of scientists, such as the physiologist Claude Bernard and the psychiatrist Albert Lemoine. In every case, Ravaisson found either too strong an emphasis on the dependence of the "spirit" upon material causes or an identification of ideas with strictly logical, hence analytical, reason. Whereas one set of philosophers tried to explain the mind in terms that were inappropriate, the other failed to ask the central question of why the mind operated as it did. Neither group could explain our undeniable feeling of being active causes; neither could see why the spirit needs both analysis and synthesis.

Whether the object of our thinking is the external or the internal world, it will be found that we have to use two absolutely general metaphysical principles, that of an infinite reality and that of limitation. The dialectical reason for this is that every analytical sentence distinguishes between parts of a whole and no whole can be discussed except by reference to its constituent parts. But Ravaisson did not rest his doctrine on this dialectical argument. On the contrary, he believed that history had shown that every philosopher presupposes these principles, whether he knows it or not. The tendency of the history of philosophy is toward the progressive realization of this truth. It is implicit in all philosophy and is steadily becoming explicit. Ravaisson's report thus presented not only an exposition of contemporary French philosophies but also a theory about the history of philosophy.

In a shorter study, *De l'habitude*, written as a thesis at the Sorbonne in 1838, Ravaissou returned to the problem raised in Maine de Biran's prize-winning essay on the influence of habit on thinking. Ravaissou's study is of special historical interest since it forms the nucleus of the philosophy of Henri Bergson.

At the beginning of his argument Ravaissou laid down a fundamental distinction between the roles played by space and time in our lives. "Space," he said, "is the most obvious and elementary condition and form of stability or permanence; time the universal condition of change." Corresponding to these two basic principles are matter and life respectively. In matter there is no individuality and no possibility of habit, a point that Ravaissou probably encountered in his study of Aristotle. Life, on the contrary, forms a world of its own, a world that is internal to the living being. A set of oppositions follows, that of necessity (matter) versus that of "nature" (life), a set that echoes the two realms of necessity and freedom elaborated by Schelling. The repetition of a change modifies "nature," and the living being swings between the limitations of its material conditions and its own inner freedom. As the forms of life develop, their power of spontaneous action becomes greater, so that although the inorganic is timeless, life implies a "definite continuous *durée*." As we move up from vegetable to animal to human life, we find that whereas sensory impressions become weaker when repeated, our powers of movement become stronger and stronger.

Corresponding to these dualities is another. Within the human soul are the two powers of understanding and of activity. The understanding sees everything under the aspects of diversity, quantity, and space; the power of activity appears primarily in our feeling of effort, which is gradually reduced by habit. Habit transforms voluntary movements into instinctive movements. Voluntary movements could not be made if there were no resistance from without, but for them to be made at all requires that somewhere there be an undetermined center of activity, which is the will. And when one asks what the will is seeking, the answer is that it seeks the good, or God. It is not difficult to see in these views both the influence of Schelling and the anticipation of Bergson.

RAWLS, JOHN

(1921–2002)

John Rawls is widely regarded as one of the most significant political philosophers of the twentieth century. Educated at Princeton University, he taught at Cornell University and the Massachusetts Institute of Technology before joining the faculty of Harvard University in 1962. Rawls's *A Theory of Justice* (1971) revitalized political theory as an academic discipline and rejuvenated interest in the substantive social issues that had long been neglected by academic philosophers. Rawls continued to refine and defend his theory in a series of articles and lectures, the most important of which he revised and collected in his 1993 work *Political Liberalism*. In 1999 *The Law of Peoples* extended his theory to questions of international relations, and in the next two years, despite declining health, he published *Lectures of the History of Moral Philosophy* (2000) and *Justice as Fairness: A Restatement* (2001).

JUSTICE AS FAIRNESS

The primary objective of Rawls's political theory is to articulate and defend a conception of justice for a modern democratic regime. The theory begins with the idea of society as a fair system of cooperation between free and equal persons. The principles of justice for such a society characterize its fair terms of cooperation by specifying its citizens' basic rights and duties and by regulating the distribution of its economic benefits. To formulate his particular conception of justice, Rawls

invokes the familiar theory of the social contract, according to which the legitimate rules for a society are arrived at by the autonomous agreement of its members. Rawls's version of the contract theory is distinctive, however, in its insistence on the essential fairness of the point of view from which the agreement itself is conceived. This enables Rawls to appeal to the justificatory force of *pure procedural justice*, the idea that the fundamental fairness of a procedure can ensure the justice of its outcome provided that there is no independent criterion for the justice of that result. Fairness thus characterizes both the terms of the contractual agreement and the conditions in which that agreement is made. Rawls appropriately names the resulting theory *justice as fairness*.

Rawls's contractarian or *constructivist* theory represents this fundamental ideal of fairness by situating the contracting parties in a hypothetical *original position*. The most important feature of this theoretical model is the *veil of ignorance*, which denies to the parties any knowledge of their actual natural endowments, their social position, or even their conception of what makes for a good life. As a consequence, the parties cannot determine how proposed principles would affect their interests personally. The veil of ignorance thereby reflects our conviction that it would be patently unreasonable to allow principles that favored any individuals or groups merely in virtue of their possession of morally arbitrary attributes such as their race or sex, or because they happened to affirm a particular religious or philosophical doctrine.

THE PRINCIPLES OF JUSTICE

Though deprived of knowledge of their particular ends, attachments, and aspirations, the parties in the original position are still rationally motivated to further their conception of the good, whatever it is. They also have *higher-order interests* in developing and exercising the two *moral powers* that they share as free and equal beings: (1) the capacity to understand and act from a sense of justice and (2) the capacity to form, revise, and rationally pursue a conception of the good. The parties will therefore seek for themselves the best possible package of *primary goods*, those all-purpose, socially regulable opportunities and resources needed to advance those interests. Rawls's enumeration of these primary goods includes basic rights and liberties, the powers and prerogatives of offices and positions, income and wealth, and the social bases of self-respect. Assuming that a society has reached a minimal level of economic development, Rawls argues that the following two principles for allocating the primary goods would be selected:

- a. Each person has an equal right to a fully adequate scheme of equal basic liberties which is compatible with a similar scheme of liberties for all.
- b. Social and economic inequalities are to satisfy two conditions. First, they must be attached to offices and positions open to all under conditions of fair equality of opportunity; and second, they must be to the greatest benefit of the least advantaged members of society. (Rawls 1993, p. 291)

Since the first principle is given absolute priority over the second, Rawls argues that the basic liberties guaranteed by it, such as freedom of religion or the right to run for political office, cannot be sacrificed for any amount of personal or collective economic benefit. Such liberties can be limited only to protect the central range of application of other conflicting liberties, as when the right to a fair trial necessitates some restrictions on the freedom of the press. Specific rights are included in the protection of the first principle if agents in the original position would rationally require them. For example, freedom of religion would be insisted on by the parties, for they could not risk the possibility that their religion, should they have one, would be a minority faith subject to repression by a dogmatic majority.

The second principle deals with economic and social primary goods such as income and wealth. Its second condition, the so-called difference principle, stipulates that any departures from equality of resources can be justified only if the resulting inequality benefits the least advantaged members of society. Thus, positions that require the development of talents and the expenditure of extraordinary effort might deserve greater economic rewards, but only if the increased productivity generated by such a differential would improve the condition of the least well off. Rawls argues that this requirement would be the reasonable and rational choice of individuals who, because of the fairness conditions imposed in the original position, did not know their natural and social endowments and therefore could not determine their actual position in the social order.

The first part (of the second principle) stipulates that even the limited inequalities that would satisfy the difference principle are permissible only if the positions that give rise to them are open to all under conditions of *fair equality of opportunity*. This strong requirement goes beyond mere prohibition of discrimination based on arbitrary features such as gender or race. It demands that all individuals of like natural ability and similar motivation should have the same opportunities throughout their entire lives, a requirement that obviously necessi-

tates equal access to education, health care, and other social resources.

STABILITY

A viable political theory, Rawls insists, must be practical. The well-ordered society that it mandates must be feasible and stable given realistic economic, cultural, and psychological assumptions. In *A Theory of Justice* Rawls argues that a society regulated by justice as fairness would be stable since the laws of moral psychology show that its members would tend to acquire and maintain a common comprehensive moral doctrine that would sustain it. In *Political Liberalism*, however, he admits that a liberal, nonauthoritarian regime would be characterized by a plurality of reasonable, though incompatible comprehensive religious and moral doctrines. Nonetheless, he believes that the requirement of stability can be met by justice as fairness if it is understood as a political theory. As such, it regulates only the *basic structure* of society: the background institutions that specify political and civil rights and that determine entitlements to other socially regulated goods. Members of a well-ordered society may therefore hold deeply conflicting comprehensive religious and moral views, yet still endorse a common political conception of justice as the focus of an *overlapping consensus*. Moreover, Rawls stresses that this consensus can be more than a mere *modus vivendi*, a practical compromise based on a tenuous balance of power. Rather, it can express a genuine moral commitment that reflects ideas and values implicit in the society's political culture, such as its conception of the citizen as a free and equal person and its willingness to rely on reasonable standards of *public reason* in the conduct of its political affairs.

THE LAW OF PEOPLES

Rawls applies his principles of justice to individual, self-contained societies and not to humanity at large. He does not think, for example, that the difference principle should be applied globally. Rather, he argues for a *law of peoples*, a more limited set of obligations on just societies, first, to obey some traditional canons of international law (such as to wage war only in self-defense and to honor basic human rights) and, second, to aid peoples that lack sufficient resources to support just social institutions. These duties, he argues, would be agreed to in a second original position, populated now by representatives of just or "decent" peoples who are behind a veil of ignorance with respect to the particular societies that they represent.

REFLECTIVE EQUILIBRIUM

Rawls's methodology has been as influential and as controversial as his substantive views. Declining to ground his views on any deep metaphysical or other philosophical truths, Rawls maintains that political theory should formulate a coherent set of principles that accounts for the considered convictions that we actually hold. The process goes beyond mere summarization of particular considered judgments, however, for it also postulates theoretical models, mediating ideas, and principles at all levels of generality. All judgments and principles are held open to revision in light of other aspects of the theory, until no further changes are needed to develop a compelling and coherent view. The resulting theory is then said to be in *reflective equilibrium*. It is also *objective*, Rawls contends, because it would gain the assent of all reasonable individuals on due reflection.

REALE, MIGUEL

(1910–)

Miguel Reale, the Brazilian philosopher of law, historian of ideas, and politician, was a professor of law and a rector at the University of São Paulo, where he founded the Instituto Brasileiro de Filosofia and its journal, *Revista brasileira de filosofia*. Reale is a prolific author, and his books embrace the full range of his concerns, although his greatest contribution lies in the philosophy of law.

Reale has developed an analytical method (derived from German phenomenology and Italian historicism) that he calls “critical ontognoseological historicism.” Rejecting both traditional realism and idealism, he locates the transcendental conditions of human experience and knowledge in a fundamental and inseparable correlation of subject and object. These conditions are mutually implicit and reciprocally necessary and are comprehensible only as moments in a polar dialectical process. Man’s being emerges only through his own historicity, as values are realized in time through his conduct. The person finds his essence (*ser*) in what he ought to be (*dever-ser*), and he is the source of all values. Values are possible only where there are persons, and personality consists in conduct that is comprehensible only with reference to ends and values. A phenomenological description of human action reveals its essential orientation toward ends that represent values determining action and serving as the foundation of the “ought-to-be” in which man finds his essence. Reale interprets human history as a process through which values are converted into ends,

accompanied by cultural crises whenever a new generation refuses to recognize the value of traditional ends.

Legal phenomena are basic to the realization of values in common. In law, two persons are joined in a polar nexus of common needs. Reale distinguishes three traditional approaches to the understanding of the nature of law. Sociologism interprets law as a positive fact and explains it in sociological and historical terms. Neopositivism interprets law as the expression of the operative norms of a given society and analyzes its function therein. Culturalism interprets law as axiological in nature and investigates the transcendental conditions that make it possible. Reale rejects all three as merely partial interpretations. Fact, norm, and value, in his view, are dialectically unified and not merely juxtaposed. Law is a fact through which values are made concrete in history and through which intersubjective relations are normatively ordered.

REALISM

In the early history of philosophy, particularly in medieval thought, the term *realism* was used, in opposition to nominalism, for the doctrine that universals have a real, objective existence. In modern philosophy, however, it is used for the view that material objects exist externally to us and independently of our sense experience. Realism is thus opposed to idealism, which holds that no such material objects or external realities exist apart from our knowledge or consciousness of them, the whole universe thus being dependent on the mind or in some sense mental. It also clashes with phenomenalism,

which, while avoiding much idealist metaphysics, would deny that material objects exist except as groups or sequences of *sensa*, actual and possible.

THE POLEMIC AGAINST IDEALISM

At the close of the nineteenth century, idealism was the dominant Western philosophy, but with the opening of the twentieth century, there was an upsurge of realism in Britain and North America, associated in the former with G. E. Moore, Bertrand Russell, and Samuel Alexander and in the latter with William James (despite his pragmatism), the new realists, and later the critical realists. Before a discussion of realist doctrine, a brief survey may be given of its attack on idealism.

The claim that material objects cannot exist independently of mind had been made on various grounds. First, the analysis of perception, especially of illusions, was held to show that our knowledge was limited to groups of sensations “in the mind” or to products of the synthesis or interpretation of sensory data. Later idealists, under the slogan “all cognition is judgment,” stressed the role of judgment and interpretation in perception, concluding that objects as we know them must be largely or even wholly the work of the mind. Second, physical objects cannot exist independently of the mind, for whatever is known is relative to the mind that knows it. This is the “egocentric predicament”—that one can never eliminate the “human mind” from knowledge and discover what things are like apart from one’s consciousness or, indeed, whether they exist when they are not known, for the discovery itself involves consciousness and thus would be knowing. This may also be stated in terms of the doctrine of internal relations—that the nature of anything is grounded in and constituted by the relations it has with other things; no two related things could be what they are if the relation between them did not exist, and so, as a special case of this, physical objects could not be as they are apart from their relation to the mind that knows them.

STATUS OF THE OBJECTS OF PERCEPTION. Concerning the analysis of perception, realist philosophers have devoted considerable attention to showing that in perception we obtain knowledge of external physical objects either directly or by means of *sensa*. Their accounts of perceiving and their solutions to the problems raised by illusions and other facts of perception differ greatly, but they agree in rejecting the view that things cannot exist unperceived. G. E. Moore’s influential “Refutation of Idealism” consisted in an attack on this thesis, which, follow-

ing George Berkeley, he stated as “*esse is percipi*” (“to be is to be perceived”). He claimed that in maintaining this the idealists had failed to distinguish between the act and the object in sensation. They had confused the sensation of blue with its object blue or, when claiming to distinguish them, inconsistently treated them as identical.

Sensations are alike in being acts of awareness but differ in what they are awareness of. Once the object is distinguished from the awareness of it, there is no reason to deny its existence unperceived. Further, in no other situation have we a better claim to be aware of something distinct, so that if sensations are not cases of awareness of objects, no awareness is ever awareness of anything, and we cannot be aware of other persons or even of ourselves and our own sensations. Fundamentally, Moore’s thesis concerning sensations rested on introspection; it has been denied on a similar introspective appeal by upholders of the adverbial analysis of sensing, and Moore himself later had grave doubts about it. Commonsense realists would say that he conceded too much in talking of sensations and interpreting “being perceived” (*percipi*) as “being sensed” (*sentiri*); the proper starting point is our awareness of material objects. But Moore was no doubt accepting the usual conclusions from the argument from illusion. From his analysis arises the question: “What is the object of sensation?” The answer, “A sense datum,” posed the problem, which he never solved, of the relation between sense data and material objects. It was met by others with some form of representative realism or, more usually, phenomenalism. Phenomenalism, however, particularly if coupled with the adverbial analysis of sensing, means the abandonment of realism. The idealist stress on judgment in perception was at first little discussed, but critical realism and the sense-datum theory later offered more plausible alternatives.

THE EGOCENTRIC PREDICAMENT. The realist attack on the egocentric predicament involved considerable discussion, particularly in the United States, and led to some close argument—for example, in attempts to show that the idealist principle led to self-contradiction or circularity when developed. The egocentric predicament was claimed to have no idealist implications. To infer from it that nothing exists outside consciousness is simply fallacious—that one cannot discover *X* does not mean that *X* does not exist or even that it is unreasonable to suppose that *X* exists. Indeed, if it were true that things could not exist apart from a person’s consciousness of them, neither, presumably, could other persons; the predicament would imply an incredible solipsism.

Nor is there any evidence of the lesser conclusion that objects outside consciousness would be quite different. No conclusion about the degree of distortion introduced by our consciousness follows from its ubiquity, and it may be negligible; one can only try to discover the degree by comparing various methods of knowing. (Distortion by the method of observation may be serious in atomic physics, but the same argument that establishes distortion there shows it to be negligible for objects larger than atoms.)

The predicament is sometimes stated in terms of the privacy of experience—a person can never know anything that is not a content of his private experience. This, however, is question-begging in that it simply denies the ordinary assumptions that we are aware of other persons and external public objects. There may be grounds for denying these assumptions in certain cases, but such grounds rest on evidence of causal processes and of illusions, evidence that is largely obtained from other persons, or with the aid of public objects, or from comparisons with perceptions of public objects. Further, though more dubiously, Wittgenstein has argued that if we had only private experiences, not only would they be incommunicable, but also we could not describe or speak about them even to ourselves, for the use of language implies rules that are communal and have to be established and checked with respect to public objects.

Against the doctrine of internal relations it was claimed that relatedness is compatible with independence, that the same thing can enter into a variety of relations without losing its identity. This seemed so obvious that James confessed to finding it “weird” to have to argue for it. (Anticipating a contemporary approach, he accused the idealists of confusing linguistic or conceptual differences with factual ones; in referring to two relations of an object, our phrases and thoughts differ, but there is no corresponding difference in the object itself.) As the realists were defending what in their eyes was obvious, they were forced into detailed criticism rather than into the kind of positive thesis that can be readily summarized.

This battle was certainly won by the realists in that few English-speaking philosophers in the twentieth century espoused idealism. Indeed, to anyone coming from contemporary discussions, the controversy has an air of unreality. Partly this is because in a climate of thought that respects common sense and science, realism seems so obvious a starting point that it is difficult to explain how the idealist view ever seemed plausible; partly it is because current idioms, issues, and logical presuppositions are so

different from earlier ones. Granted, however, that material objects exist independently of our perception, the difficulties facing a realist account of this perception still remain and cause serious divisions among realists.

DIRECT REALISM

Direct realism is the general view that perception is a direct awareness, a straightforward confrontation (or in touch, contact) with the external object. It may be further subdivided according to the various attitudes then taken toward illusions and hallucinations. In contrast, there are the various types of indirect or dualist realism, which claim that perception is primarily of mental representations of the external object, as in traditional representative realism, or that our perception of the external object is by means of private, mental *sensa*.

NAIVE REALISM. Naive realism is the simplest form of direct realism and is usually alleged by philosophers to be an innocent prejudice of the average person that has to be overcome if philosophical progress is to be made. It is normally stated in terms of sensible qualities or *sensa*. When we look around us, we can distinguish various colored, shaped expanses that we suppose to be the surfaces of material objects, we may hear various sounds that we suppose to come from such objects, we may feel something smooth and hard that we suppose to be a table top, and so on. Naive realism claims that these suppositions are all correct—that the shapes, colors, sounds, and smooth, hard expanses (the sensible qualities) are always the intrinsic properties of material objects and in sight and touch are their surfaces.

Such a claim can easily be shown to be erroneous by the argument from illusion. When *A* looks at the table from above, he sees a round expanse; when *B* looks at it from a distance, he sees an elliptical one. Without self-contradiction, however, the round and elliptical shapes cannot both be the surface of the table—that is, an intrinsic property. Similarly, when *C*, who is color-blind, looks at a red book, he sees a black shape that, again, cannot be the surface of that red book; when *D*, a drunkard, sees snakelike shapes on the bed, they are not real snakes. Such examples may be multiplied indefinitely and dispose of naive realism as thus stated, but commonsense realists would say that the doctrine misrepresents the views of the average person and that philosophical discussions of it beg the question in favor of dualism by speaking of sensible qualities or *sensa* as distinct from physical objects.

NEW REALISM AND THE SELECTIVE THEORY. The new realists—E. B. Holt, W. T. Marvin, W. P. Montague, R. B. Perry, W. B. Pitkin, and E. G. Spaulding—are notable chiefly for a common realist platform published in 1910 and expanded in 1912 and for their polemic against idealism. Their realism was carried to the Platonic extreme of claiming real existence for logical and mathematical entities, and they had difficult and conflicting views about consciousness. Without, however, pursuing these, we may note their main attempt (by Holt) to deal with illusions, which is a version of what is often called the selective theory. The essential points of this theory are, first, all the various appearances of an object are its intrinsic, objective properties and are directly apprehended by the percipient. For example, the table that looks round to *A* and elliptical to *B* is intrinsically both round and elliptical; the mountain that looks green close up and blue in the distance is both green and blue. There is nothing private or mental about such appearances, for they can be photographed, as can mirror images and various optical illusions. Second, the function of the nervous system and of the causal processes in perception is to select and reveal to the percipient one property from each set of properties, for example either the elliptical or the round shape of the table.

One difficulty in this is that it does not really account for error. If we are always directly aware of actual characteristics of objects, what sense does it make to talk, as we do, of illusions, mistakes, or misperceptions? Another lies in the weakness of the selective theory compared with the generative theory, adopted by dualist realism, which states that the sensible qualities, or *sensa*, are “generated,” by the action of the object on the sense organs and nervous system and thus are not intrinsic properties of external objects. The usual reasons for preferring the generative theory are, on the one hand, that it is self-contradictory to say the table is intrinsically both round and elliptical or the mountain is intrinsically both green and blue. Furthermore, objects must be incredibly complex if they are to possess all these shapes and colors, plus, presumably, qualities corresponding to the queer appearance of objects when one has taken mescaline or suffers from giddiness or double vision. On the other hand, it is not clear how the nervous system specifically responds to or selects one of the various shapes, colors, and so on. This is particularly so in such cases as color blindness, drugs, and double vision, where the different appearances are the result of differences in the percipient and where the pattern of light waves can be detected as already differentiated for the shape and color normally perceived.

The generative theory, however, fits the facts of the causal processes quite well; it is natural to suppose that the generation of the sensory experience and its *sensum* occurs at the end of the causal chain that extends from object to brain by way of sense organ and nerves. This is confirmed by the reproduction of such experiences in mental imagery (presumably because the appropriate brain activity recurs), by the sensations resulting from electrical stimulation of the brain, and by the time lag that may occur between an event and our perception of it—all things that the selective theory cannot explain. Also, the generative theory can explain how voluntary selection occurs. When we turn our head to look at *X* rather than *Y*, we are allowing light from *X* rather than *Y* to strike our eyes and thus bring into being the *sensa* appropriate to *X*. As to photographing appearances, the photograph corresponds to the retinal image, not the *sensum*—that is, it reproduces not the perceived appearance but an intermediate cause of it; to enter into human experience, it must, in turn, be perceived by generating *sensa*.

PERSPECTIVE REALISM AND THEORIES OF APPEARING. The first objection to the selective theory—that it makes objects possess contradictory qualities—might be met by stressing that shapes, colors, and other qualities are not intrinsic but relative properties. The table is round from here, elliptical from there; the mountains are green in this light, blue in that light, and so on. This idea has been coupled with direct realism in a number of similar theories: perspective realism (E. B. McGilvary), objective relativism (A. E. Murphy), or the theory of appearing. (This last name was given by H. H. Price to a view put forward by H. A. Prichard. Roderick M. Chisholm, however, uses it more widely, and it is convenient to class all these views as theories of appearing.) Their central point is that direct realism can deal with illusions, or at least perceptual relativity, by saying that sensible qualities are not possessed by the object *simpliciter* but are always relative to some point of view or standing conditions. We always perceive sensible qualities in some perspective—spatial, even temporal (we see the distant star as it is from here and now), or illuminative (the object as it is in this light). (In such theories the shape, color, and so on are possessed by the object at its own location but are perceived subject to perspective, meaning from a viewpoint. In contrast, Bertrand Russell had a phenomenalistic theory of “perspectives” that were spread through space as possible *sensa* and actualized by or in the percipient.)

Such perspective-realist statements as “The table is round from here” sound forced, for the natural word to

use is *looks*, not *is*, and it is possible to express this kind of direct realism in terms of looking or appearing. Physical objects simply are such that they appear different from different positions, and we see them as they appear from a viewpoint or in certain conditions. Thus, we may see the round table looking elliptical from here, but even so it is still the table that we see.

Thus far the theory is trite and does little more than state the situation in a way that dualists could accept and then claim to analyze. To be distinctive, it must, as its essential characteristic, separate directness and incorrigibility. Sense-datum theory links the two, assuming that if we see an object directly, we must see it as it actually is. Thus, when the round table looks elliptical, we do not see it directly; what we see directly is an elliptical datum belonging to it.

In contrast, theories of appearing must simply claim that seeing an object directly is compatible with variation or even error in perception, so that we still see it directly when according to viewpoint, lighting, and similar factors, it appears really different from what it is. (Some might object that the theory cannot admit that perceiving is ever erroneous. Perspective realism treats all properties as relative and all perspectives as equal—the table is round from here, elliptical from there, but not round in itself; similarly all appearances should be treated as equally valid. Nevertheless, it seems more plausible to treat some appearances as privileged; in some conditions we see the real shape, the round object appearing as it is—that is, round. It may be considered a weakness of the perspective theory that it does not take into account the fact that objects do seem to have real [measured] shapes and volumes absolutely, not relative to a viewpoint.)

The approach of theories of appearing may deal plausibly with perspectival and similar variations, but it has two main defects. First, not all variations are of this nature. In double vision or mescaline illusions there seems to be existential appearing—there may appear to be two or even many tables when we look at one table. Price has argued that this cannot really be a case of directly seeing one table, for it differs significantly from seeing something merely with different properties, such as seeing a brown table instead of a black one. Also, many illusions are the result of subjective factors, so that it is difficult to say that one has a genuine perspective.

Talk of physiological perspectives is little help. “The bottle from here” is not on a par with “the bottle as it is to someone who has taken mescaline,” for mescaline may cause a range of different experiences. Similarly, when a sentry at night is convinced he sees the enemy approach-

ing but only a shadow is there, is he directly seeing the shadow in some special perspective, such as “the way it is to an anxious sentry” or “looking like a man”? Another anxious sentry might see it as a shadow and say it does not look like a man. And in a full hallucination there is no object at all. Second, theories of appearing cannot deal plausibly with the causal processes in perception since they have to adopt the selective theory. Further, we do know with varying degrees of completeness why things suffer perspectival distortion or how they cause illusion. The explanations concerned are often in terms of the causal processes and so seem to call for the generative theory and the abandonment of direct realism.

COMMONSENSE REALISM. In the tradition of Thomas Reid, revived by G. E. Moore, many twentieth-century British philosophers defended what they took to be a commonsense view of perception. Moore’s defense was primarily of the certainty of such simple perceptual statements as “This is a hand”; he argued that denial of these statements leads to inconsistency in beliefs and behavior and that the grounds for their denial involve propositions less certain than they are. However, his analysis of such statements in terms of sense data led away from direct realism and the commonsense view of the nature (as opposed to the reliability) of perception.

Defense of common sense became particularly associated with the Oxford linguistic analysts. Strong critics of the sense-datum theory (unlike Moore), they also reject the traditional naive realism as unfair to common sense—after all, we do not think that everything we see is the surface of a physical object (certainly not lightning flashes or rainbows) and are quite ready to admit that we often see things looking different from what they are. Although quarreling with the common philosophical uses of *appear*, *direct*, and *real*, they maintain a direct realism not unlike the theories of appearing and attempt to show in detail that in so-called illusions, including reflection and refraction, we do actually see the physical object concerned. Criticism has been made of the view that hallucinations are indistinguishable from normal perception, and more positively it may be claimed that hallucinations are mental images confused with perceptions owing to such special circumstances as drugs or fever. It is doubtful whether this can explain all the cases, and the role of the psychological processes—for example, in attention or in the influence of expectation and past experience—throws doubt on the directness of perceiving.

Some attempt has also been made to deal with the causal processes, but not very convincingly. Attacks have been made on the dualist interpretation for making it seem that we perceive something in our heads and not external objects and for the view that perceiving involves awareness of sensations. But linguistic analysts have said little of a positive nature; their main attitude is that the causal processes are at most only the conditions of perception and are the concern of the scientist but that the philosopher is concerned with perception itself, which is a skill or instantaneous achievement, not a physical process or the final stage of one. Unfortunately, scientists generally claim that the study of the causal processes requires representative realism, and even if the average person does not bother about them, an adequate philosophical theory cannot ignore the causes and conditions of perceiving, particularly since the explanation of illusions depends on them.

INDIRECT OR DUALIST REALISM

Many realists are persuaded by the argument from illusion and by their study of the causal and psychological processes in perception to reject direct realism and to distinguish between external material objects as the causes and ultimate objects of perceiving and private *sensa* that are the mental effects of brain processes due to the action of those objects on the sense organs. The classic form of this general view was the representative realism (also called the representative or causal theory) of René Descartes and John Locke, which is still maintained in principle by many scientists. From Berkeley on it suffered much criticism, and its defects led to its being unpopular among philosophers. Modern attempts have been made, however, to remedy these defects and to propose an acceptable theory. The resultant position we shall discuss as critical realism. Although they start from an analysis of perceptual experience and do not argue from the causal processes underlying it, supporters of the sense-datum analysis who are not phenomenalists are forced into one of these kinds of dualist realism.

REPRESENTATIVE REALISM. In what is loosely called “seeing a table,” light rays reflected from the table strike the eye, cause chemical changes in the retina, and send a train of impulses along the optic nerve to the brain. The resultant brain activity is then said to cause the mind of the percipient to be directly aware of private *sensa* (Locke called them “ideas”) that represent the shape, color, and other visual properties of the table. A similar account is given for the other senses. The essential point is that perceiving proper is the direct awareness of *sensa*; perceiving

external objects is redefined as perceiving *sensa* caused by them, and so all our awareness is strictly limited to *sensa*. “Represent” is usually interpreted in accordance with the doctrine of primary and secondary qualities—that is, the *sensa* resemble the object in spatiotemporal properties but not insofar as colors, sounds, smells, and other secondary qualities are concerned. Modern analogies of “representing” are the relation between a map or radar screen and the region they cover or between television or movies and the studio events reproduced.

Merits of representative realism. Representative realism has important merits. It is the easiest inference from the scientific account of the causal processes up to the brain in all perceiving and fits other scientific evidence. Thus, color blindness and deafness are the result of defects in the sense organs that so affect all subsequent stages in the causal transmission that the resultant *sensa* are different from normal. That electrical stimulation of the brain causes sensations of color, smell, and so on, according to location, seems to confirm the theory, and it can easily accommodate the time lag in perception. Further, by holding that representation does not amount to resemblance in the case of secondary qualities, it can be made to fit the distinction between the world as we see it (that is, the *sensa* grouped as ostensible objects) and the scientific account of material objects, which is in terms of colorless, tasteless, and smell-less elementary particles.

Representative realism also accounts for illusions, dreams, images, hallucinations, and the relativity of perception. Relativity and many illusions result from changes in the stimulation of the sense organs because of distance, medium, angle of sight, and other relevant factors; such changes affect all that follows and so vary the *sensa* caused. Other illusions are the result of misinterpretation of *sensa*. In imagery and dreams the brain activity that occurred in corresponding perceptions is reactivated as the result of internal causes and so brings about the recurrence of similar *sensa*. (The reactivation may be only partial, and the resultant data may be consciously or unconsciously altered by the mind.) Hallucinations are also imagery. Since the images are of a similar character to normally perceived data and are the result of a similar immediate cause in the brain, it is easy to see how they may merge in integrated or triggered hallucinations or how perception may be imaginatively supplemented. The standard explanation of phantom limbs—that they are sensations caused by irritation at the stump of nerves normally coming from the amputated limb—is also accommodated. As perception is confined

strictly to the effects of the causal chain, interference with it en route may readily deceive us.

Finally, representative realism has also traditionally been part of the widely accepted interactionist or dualist account of the relation of mind and body: The body affects mind in perception, mind affects the body in voluntary action. Not all who accept that theory realize that they are saddled with representative realism.

Defects of representative realism. Despite its merits, representative realism has some serious defects. If, as it claims, our perceiving is strictly awareness of the mental ideas or *sensa*, it is difficult to see how we can break out of the circle of *sensa* and observe external objects. How can we tell what these objects are like; indeed, how do we know that there are such objects? If we try to verify the existence of the table by touching it, we simply obtain more *sensa*—tactile ones—and if we see our hands touching the table, we are just having visual *sensa*. Whenever we try to peer over the barrier of *sensa*, we just get more *sensa*. This difficulty undermines the analogies used in the theory. Representation is conceived of as something like mapping or photographing, but we know a map represents or a photograph resembles an object because we can observe both and compare them; ex hypothesi, however, we can never strictly observe both objects and *sensa* to compare them. Observing objects is just observing *sensa*, so we do not know that objects and *sensa* resemble each other in primary but not in secondary qualities.

It is often said that representative realism not only leads to skepticism but is also self-refuting, cutting off the branch on which it sits. Its premises and evidence assume that we discover the action of the objects on the sense organs by observing them. Its conclusion—all our perception is of *sensa*—denies that we can do this. However, there would be self-refutation only if the conclusion contradicted the premises, which it need not do if carefully stated. The theory may be regarded as really distinguishing two types of perceiving: perception in its everyday meaning, which is discovering about external objects by means of the senses, and perception proper—direct awareness of *sensa*. It is saying that the first type really amounts to or, better, is really effected by the second type. Thus, granted that by perceiving *sensa* we do discover the nature of objects (at least insofar as their primary qualities are concerned) and their interaction, the first type of perception and the evidence it gives still hold good, and there is no self-refutation. Nevertheless, the skepticism remains, for since our direct awareness is limited to *sensa*,

we do not know that there are objects or what they are like; we only suppose or guess that and what they are.

Even though representative realism need not be self-refuting, it is open to the charge of circularity if considered as an attempt to explain perceiving. It appears simply to transfer perceiving as ordinarily conceived (a face-to-face confrontation) from outside to inside the person; perceiving external objects is now put forward as perceiving private replicas of them, for we look at maps and television pictures in the same way that we look at the countryside. Even if we say perceiving objects is achieved by perceiving *sensa*, there is the same duplication of perceiving, which is thus explained in terms of itself.

Representative realism's view of the mind is rather crude, for it tends to speak almost as if the self or mind were a little person in the head looking at pictures of the outside world. It is not clear how *sensa* can exist in an unextended mind, since they apparently possess shape and size; nor is any serious attempt made to fit the psychological processes of perception into the general scheme.

There are special difficulties for those versions of the theory that claim that in perceiving objects we infer the existence or nature of external objects from our *sensa*. Apart from the inevitable dubiety of such inference, the main objection is that we are never conscious of these inferences nor are we aware of *sensa* as such—that is, as private mental data. If we were, it is difficult to see how the notion of publicly observable causes would occur to us. But the representative theory may simply say that the *sensa* seem to be external (or externally caused) from the start and that any inference is justificatory to deal with skeptics. (This seems to have been Locke's view in his *Essay concerning Human Understanding*, Bk. IV, Ch. xi, Sec. 2.)

CRITICAL REALISM. Critical realism is the name primarily given to the views expressed by the American authors of *Essays in Critical Realism*—namely, that the data in perception (that is, what is intuited, what we are directly aware of) are not actually part of external objects but are “character-complexes ... irresistibly *taken*, in the moment of perception, to be the characters of existing outer objects” (p. 20). In veridical perception these characters are the characters of external objects; in illusions they are not. The authors were unfortunately divided over the nature of this datum or character complex, Durant Drake, A. K. Rogers, George Santayana, and C. A. Strong claiming that it was not a mental existent or any kind of existent, but only an essence, a mere logical entity or uni-

versal, whereas A. O. Lovejoy, J. B. Pratt, and R. W. Sellars held that it was a mental existent, a content of sensory experience. It is difficult to grasp what the datum can be if it is not a mental content or existent, and so the second version is the more plausible and is adopted here. Although clearly dualist, it should not be confused with representative realism; in fact, it provides remedies for representative realism's main faults.

The critical realists held that the root of the troubles of representative realism lay in its failure to analyze perceiving or perceptual knowledge. Accepting the ordinary notion of perceiving as intuiting, which means a direct awareness or confrontation, and finding that because of the causal processes and of illusions such awareness was not of external objects, Locke concluded that it must be of intramental ideas and so imprisoned us in the circle of such ideas. The more reasonable conclusion, however, would be that this ordinary notion of perceiving is wrong and that a more careful analysis is needed. This will show that an essential feature of perceiving, even as ordinarily understood, is that it is the way we discover the existence and nature of external objects—that it is, in fact, a claim, often justified, to knowledge. If we appreciate this from the start, we shall not be tempted by the apparently intuitive character of perceiving into an analysis that limits it to ideas, and if we remember that this knowledge claim is not always justified—that is, that there are illusions and errors—we shall avoid the other pitfall of direct realism, in which error becomes inexplicable.

The next step is to realize that though it involves an intuition or direct awareness, perceiving is much more than this. It also involves an active external reference, as is implied by the knowledge claim; we refer this intuited mental content or character complex to an external object—that is, we explicitly judge that it is, or is the character of, an external object or we unreflectingly take it to be this or we immediately react to it as if it were an external object. These modes of reference are differently stressed by different writers, but the point seems to be that they occur in varying degrees according to circumstances. Our perception is sometimes an explicit identification or judgment, or at least it immediately issues in one—for example, we say, “Here’s our bus” or “There’s Tommy”; more often we just see that it is Tommy without formulating any judgment, or our perception that it is our bus and our starting to go and catch it seem indistinguishable, for the reference to the external object is manifest in an immediate physical response.

All the same, in contrast to the behaviorists, the critical realists stressed that there was an intuited mental

content, the character complex of which we were directly aware. Attempts were made to fit the analysis in with current psychology by explaining how this external reference arose in childhood—the apparent externality of the content was with us from the beginning of perceptual discrimination, largely because the external reference was founded in physical response to the object.

There is some similarity between this “reference of an intuited datum to an external object” and the “taking for granted that a sense datum belongs to a material object” of Price’s sense-datum theory, especially since both stress that no distinction between datum and object is drawn by the percipient at the time. But there is a difference in starting point and emphasis. Price began with sense data, treating them as distinct existents and willing to allow that material objects consisted of them. This branch of critical realism began with knowledge of external objects, but, being mental, the content or datum distinguished within it was not regarded as capable of distinct existence and was very difficult—much more so than Price thought—to isolate even subsequently from the associated reference. Also, reference covered a wider set of activities than taking for granted, for it also involved the bodily reactions. In order to stress the relative subordination of the datum, some critical realists spoke of perceiving external objects by means of, guided by, or mediated by, the datum.

Since critical realism can agree that the datum is generated, it is free from the difficulties of the selective theory and can share in the advantages of representative realism. In this version it seems able to avoid the latter’s worst faults. There is no self-refutation, for from the start perceiving is always perception of external objects by means of the intuited data, an analysis that does not deny that we perceive such objects. There is no duplication or circularity, for the direct awareness of the datum is not a replica of perceiving; insofar as it can be distinguished at all, it is much less complex than perceiving, for it involves no identification with external objects and is not in itself directed on them—hence, the map and movie analogies are essentially faulty. Common sense is not being offered an explanation of perceiving in terms of perceiving; it is being shown that perceiving is far more complex than common sense supposes, involving not only causal processes that bring about the datum or mental content but also the psychological processes of reference or response.

Moreover, there need be no skepticism. True, in perceiving we only take the datum to be an external object or its properties, and this may, of course, be erroneous. In a

sense it is always erroneous in that the datum or content is never the object, but normally the taking or reference is correct to the extent that we are perceiving an external object and that the intuited characters also do characterize the external object insofar as primary qualities are concerned; to that extent we are perceiving actual properties or at least projections of them. In general, the claim that perceiving is thus far veridical and amounts to knowledge is said to be the best hypothesis to explain the order and nature of our sense experiences. The realist claim is simply that once ordinary errors and illusions are ruled out by comparing the evidence of different senses or of different persons, the simplest explanation of the situation is that there are external objects causing the sense data or contents and corresponding to them in primary qualities. And this is plausible because if we dismiss as incredible solipsism the view that only oneself and one's own sense experiences exist, then the only real alternative is phenomenalism, a view that has fatal weaknesses and really amounts to proposing a series of deceptive coincidences.

Critical realism is not fully satisfactory, however, particularly if regarded as a theory of perceptual consciousness—that is, as an account of the mental activity that goes on in perception. Thus, the alleged datum or character complex suggests a group of sense data and invites the objections discussed under the entry *Sensa*. A closer examination is required not only of the concepts of datum and reference but also of the general relation of mind and body presupposed in perception and of the nature of mental contents; above all, the theory must take full account of the numerous quasi-interpretative activities that modern psychology has found to be involved in perception.

Bibliography

GENERAL

A clear, simple introduction to the philosophical problems of perception is Bertrand Russell, *Problems of Philosophy* (London: Williams and Norgate, 1912), and a fuller one is W. P. Montague, *The Ways of Knowing* (New York: Macmillan, 1928). A good account of modern positions on perception is given by T. E. Hill, *Contemporary Theories of Knowledge* (New York: Ronald Press, 1961). Detailed summaries of many realist works are given by W. H. Werkmeister, *A History of Philosophical Ideas in America* (New York: Ronald Press, 1949). Less detailed but more intelligible is John Passmore, *A Hundred Years of Philosophy* (London: Duckworth, 1957); also see Rudolf Metz, *A Hundred Years of British Philosophy* (New York: Macmillan,

1938). Many of the works listed below deal with the topics of more than one section.

THE REALIST POLEMIC AND NEW REALISM

The main source for new realism is E. B. Holt and others, *The New Realism* (New York: Macmillan, 1912), but new realism owed much to William James; see the papers (dating from 1904) collected in his *Essays in Radical Empiricism* (London and New York: Longman, 1912). For a useful collection of articles from this early period see Roderick M. Chisholm, *Realism and the Background of Phenomenology* (Glencoe, IL: Free Press, 1960). Among other important and often closely reasoned articles are R. B. Perry, "The Ego-centric Predicament," *Journal of Philosophy* 7 (1) (1910): 5–14; Bertrand Russell, "On the Nature of Truth," *PAS* 7 (1906–1907): 28–49; and G. E. Moore, "The Refutation of Idealism," in his *Philosophical Studies* (London: Routledge, 1922), to which compare W. T. Stace's counterattack, "The Refutation of Realism," *Mind* 43 (170) (1934): 145–155. For a general summing up in favor of realism, see D. C. Williams, "The A Priori Argument for Subjectivism," *Monist* 43 (1933): 173–202, "The Inductive Argument for Subjectivism" and "The Inductive Argument for Realism," *Monist* 44 (1934): 80–107, 186–209. For a once influential direct-realism treatment of perceptual problems, see T. P. Nunn, "Are Secondary Qualities Independent of Perception?," *PAS* 10 (1909–1910): 191–218. Ludwig Wittgenstein's language arguments are in his *Philosophical Investigations* (Oxford: Blackwell, 1958), Secs. 256ff.; for criticisms see Carl Wellman, "Wittgenstein and the Ego-centric Predicament," *Mind* 68 (270) (1959): 223–233, or the symposium "Can There Be a Private Language?," *PAS*, Supp. 28 (1954).

PERSPECTIVE REALISM AND ALLIED THEORIES

Perspective realism and allied theories are stated by Evander Bradley McGilvary in *Toward a Perspective Realism* (La Salle, IL: Open Court, 1956) and in "Perceptual and Memory Perspectives," *Journal of Philosophy* 30 (1933): 310ff. Older versions are by Samuel Alexander, "On Sensations and Images," *PAS* 10 (1909–1910): 1–35, and H. A. Prichard, *Kant's Theory of Knowledge* (Oxford: Clarendon Press, 1909), Ch. 4. Despite its title, G. Dawes Hicks, *Critical Realism* (London: Macmillan, 1938), gives a theory of appearing. Such theories are lucidly discussed by Roderick M. Chisholm, "The Theory of Appearing," in *Philosophical Analysis*, edited by Max Black (Ithaca, NY: Cornell University Press, 1950). C. D. Broad, *The Mind and Its Place in Nature* (London: Kegan Paul, 1925), and H. H. Price, *Perception* (London: Methuen, 1932), criticize these theories carefully from a sense-datum standpoint, though Price's article "Illusions," in *Contemporary British Philosophy*, edited by H. D. Lewis (London, 1956), Vol. 3, defends a limited perspective realism.

COMMONSENSE REALISM

For commonsense realism see G. E. Moore's "A Defense of Common Sense" and "Proof of an External World," which are in his *Philosophical Papers* (London: Allen and Unwin, 1959), but also see his *Some Main Problems of Philosophy* (London: Allen and Unwin, 1953). The staunchest more recent defender of common sense against the argument from illusion is J. L. Austin in his lucid and lively *Sense and*

Sensibilia (London: Oxford University Press, 1962), and somewhat similar views are clearly and concisely expressed by Anthony M. Quinton, "The Problem of Perception," *Mind* 64 (253) (1955): 28–51. Gilbert Ryle's "Sensations," in *Contemporary British Philosophy*, edited by H. D. Lewis (London, 1956), Vol. III, and Ryle's *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954) try to deal also with the causal argument in a nontechnical manner. D. M. Armstrong, *Perception and the Physical World* (London: Routledge and Paul, 1961), defends direct realism but in so doing is driven toward behaviorism.

REPRESENTATIVE REALISM (OR THE CAUSAL THEORY)

For early statements of representative realism, see René Descartes, *Principles of Philosophy*, Pt. IV, and John Locke, *Essay concerning Human Understanding*. Bk. 2, Ch. 8. Representative realism is assumed by many modern neurologists, though often not under its philosophical title. Walter Russell Brain states and discusses it as "physiological idealism" in "The Neurological Approach to the Problem of Perception," *Philosophy* 21 (79) (1946): 133–146, reprinted with further consideration of perception in his *Mind, Perception and Science* (Oxford: Blackwell, 1951); he gives a further defense of his position in his *The Nature of Experience* (London: Oxford University Press, 1959). J. C. Eccles, *The Neurophysiological Basis of Mind* (Oxford: Clarendon Press, 1953), pp. 279–281, outlines the theory as if it were fact. J. R. Smythies, *Analysis of Perception* (London: Routledge and Paul, 1956), puts forward an improved form of it closer to critical realism.

CRITICAL REALISM

The main source for critical realism is Durant Drake et al., *Essays in Critical Realism* (London: Macmillan, 1920), which reveals the differences as well as agreements; see also other works by the essayists, especially R. W. Sellars's comprehensive *The Philosophy of Physical Realism* (New York: Macmillan, 1932), his general apologia, "A Statement of Critical Realism," *Revue internationale de philosophie* 1 (1938–1939): 472–498, and A. O. Lovejoy's impressive general defense, *The Revolt against Dualism* (La Salle, IL: Open Court, 1930). R. J. Hirst, *The Problems of Perception* (London, 1959), also discusses commonsense and representative realism and reaches a somewhat similar position. A primarily pragmatist view that has affinities to and criticism of critical realism is C. I. Lewis, *Mind and the World Order* (New York: Scribners, 1929).

REALISM [ADDENDUM]

Contemporary philosophical "realism" is not a single thesis but rather a diverse family of positions, unified chiefly by their invocation of certain characteristic images and metaphors. The realist about a region of discourse typically holds, for example, that our central commitments in the area describe a world that exists anyway, independently of us; that cognition in the area is a matter of detection rather than projection or constitution; and that the objects of the discourse are real things and not just linguistic or social constructions. Debates over realism defined in terms such as these persist in nearly every philosophical subdiscipline: from ethics and the philosophy of mind to the philosophy of science and the philosophy of mathematics. (Although it is common to describe a philosopher as a realist or nonrealist *tout court*, realism in one area is generally independent of realism in another, and advocates of global realism and its opposite number, global nonrealism, are comparatively rare.) Contemporary discussion is concerned in part with the evaluation of these discipline-specific realist theses. But it is also concerned (and increasingly so) with the more basic question of how exactly the realist's distinctive imagery is to be understood.

We may epitomize the realist's stance by saying that to be a realist about a region of discourse is to regard it as describing a genuine domain of objective fact. But what is it for a discourse to describe a "domain of fact"? And what is it for a domain of fact to be "objective"? These questions are usefully approached by attempting a taxonomy of the alternatives to realism. The nonrealist rejects the realist's rhetoric of objectivity. But this rejection can take a number of more determinate forms, and their variety sheds considerable light on what realism requires.

The realist's most basic commitment is to the view that statements in the target area purport to describe a world—to say how things stand with some distinctive range of objects or facts. This claim is often glossed as the minimal requirement that statements in the area be capable of truth or falsity. Realism is thus opposed at this most basic level to nonfactualism (also called irrealism or noncognitivism): the view that declarative statements in the target area cannot be evaluated as true or false and so cannot serve a descriptive function. Nonfactualist theses have been advanced mainly in moral philosophy, where it has been suggested that moral utterances serve to express emotional attitudes (emotivism: Blackburn, 1984; Gibbard, 1990) or to endorse or proscribe certain courses of action (prescriptivism: Hare, 1963; cf. Geach, 1963). But they have occasionally been proposed in other areas. Formalism in the philosophy of mathematics (the view that mathematics is a game with meaningless marks, manipulated according to formal rules) and instrumentalism in the philosophy of science (according to which theoretical statements function as uninterpreted tools for deriving predictions about future experience) are further examples of this kind of nonrealism.

To say that a region of discourse purports to describe a world is to say more than that its central commitments are apt for truth. It is to say, in addition, that they are aimed at truth—that they are typically put forward as genuine assertions about how things stand with their ostensible subject matter. Realism is thus opposed at this second level to fictionalism, the view that seeming assertions in the target area, though capable of truth, are in fact designed only to provide representations that are somehow "good" or "interesting" or "useful" for certain purposes. Fictionalist approaches have been developed mainly in the philosophy of science, where Bas van Fraassen's constructive empiricism provides a useful example (van Fraassen, 1980; cf. Churchland and Hooker, 1985). Van Fraassen agrees with the scientific realist, against the instrumentalist, that theoretical statements possess definite truth conditions and so constitute

genuine representations of unobservable structures. However, he further maintains, this time against the realist, that the truth-value of a theory is irrelevant to its acceptability from the standpoint of science. The aim of science on van Fraassen's view is empirical adequacy: the correct description of the observable world. Theories may posit unobservable things. But a good scientific theory—one that satisfies to some high degree all of the aspirations implicit in the scientific enterprise—may be largely false in its account of such matters, so long as it is a reliable guide to the observable world. In advancing a theory in what seems to be the assertoric mode, the scientist shows only that he accepts it as empirically adequate. Van Fraassen's fictionalism thus consists centrally in his contention that the endorsement of a scientific theory does not involve the belief that it is true or that the unobservables it posits exist. Generalizing, we may say that realism involves, in addition to the semantic thesis of truth aptitude, the pragmatic thesis of truth directedness, according to which the target discourse aims at truth, and the endorsement of a claim is normally an expression of one's belief that it is true. (See Field, 1980, for a fictionalist approach to the philosophy of mathematics.)

Before we have a position that is recognizable as realist we must add one further ingredient. It is not enough that our central commitments aspire to truth. They must also be true, or at least not wildly mistaken. Realism is thus opposed at this third level to a conception of the target area as involving a fundamental mistake about what the world contains. This "error-theoretic" alternative to realism is typified by J. L. Mackie's view of morality (Mackie, 1977). According to Mackie, ethical discourse purports to describe a range of objective prescriptions, constraints on action that are somehow built into the fabric of nature. But since it can be shown (Mackie held) that there are no such items, it follows that morality is based on a mistake—the entities it purports to describe do not exist; the properties it trades in are not instantiated—and hence that moral discourse demands reconstrual, if not outright rejection. A more familiar instance of the error-theoretic approach is atheism, the view that theological discourse is vitiated by the mistaken supposition that God exists. Agnostic versions are also possible, though in fact they have played no significant role outside the philosophy of religion.

A philosopher who holds that our core commitments in an area succeed in providing a true account of their intended subject matter may be called a minimal realist about that area. It is sometimes suggested that there is nothing more to realism than this minimal view

and hence that once the questions of truth aptitude, truth directedness, and truth have been settled, there is no further space for debate about whether the discourse is to be understood “in a realistic fashion.” There are, however, at least two reasons to resist this claim.

The first concerns the classification of reductionist positions. The behaviorist thesis that psychological statements can be reduced without remainder to claims about overt bodily movements and the like is clearly compatible with minimal realism about the mind. And yet the view that there is nothing more to being in pain than exhibiting “pain behavior” has generally been regarded as a clear alternative to a robust realism about mental states. It has thus become customary to insist that the realist’s commitment to the truth of our views in the target area be a commitment to their truth on a literal or face-value construal (Blackburn, 1984, chap. 5; cf. Wright, 1983). The behaviorist translation of a simple psychological statement such as “Nadja is dreaming of Paris” will typically be a long conjunction of conditional claims describing the outward behavior Nadja would exhibit if prompted by various stimuli. But this paraphrase has a very different “surface form” from the psychological claim whose meaning it is meant to capture. And this suggests that on the behaviorist’s account, the correct interpretation of psychological statements is not a face-value interpretation and hence that while he may endorse a version of minimal realism about the mental, the behaviorist should not be classed as a realist without qualification.

The second and more serious reason to resist the identification of realism with minimal realism is that minimal realism by itself involves no commitment to the mind independence or objectivity of the disputed subject matter. Immanuel Kant’s transcendental idealism has generally been regarded as a paradigmatic alternative to full-blown realism about the external world; and yet it is fully compatible with minimal realism as defined above. Objects in space and time are real, for Kant, in the sense that much of what common sense and science have to say about them is literally true. And yet there is another sense in which they are not fully real. The structure of the spatiotemporal world is “conditioned” for Kant by the structure of the mind that experiences it. Empirical investigation is therefore not addressed to a domain of fact that is altogether “independent of us.” Clearly, Kant’s position should not be described as a species of realism without qualification, its consistency with minimal realism notwithstanding.

Much of the most important work on realism has been devoted to explicating the commitment to objectiv-

ity that seems a necessary component of any fully realist position. The most natural thought is to identify objectivity directly with a straightforward sort of mind independence. A state of affairs will then count as objective if it would have obtained (or could have obtained) even if there were no minds or mental activity. But this precludes realism about the mind itself and also about any discourse in the social sciences that concerns itself with the products of human thought and action. And this is implausible. It should be possible to be a realist about psychology, for example, while conceding that the facts it describes are obviously mind dependent in the sense that they would not have obtained if there were no minds.

One influential approach to this problem is due to Michael Dummett, whose work is largely responsible for the current prominence of realism as a theme in Anglophone philosophy (Dummett, 1978; cf. Wright, 1992). On Dummett’s view the dispute over realism, though ultimately an issue in metaphysics, is best approached by recasting it as a dispute within the philosophy of language about how to construct a theory of meaning for the target discourse. A theory of meaning in Dummett’s sense is a representation in propositional form of what a competent speaker knows in virtue of which he understands his language. Dummett identifies realism with the view that a meaning theory must take the form of a classical two-valued semantic theory: an assignment of truth conditions to sentences that respects the principle of bivalence, according to which every sentence is determinately either true or false. Realism’s slogan is: To understand a sentence is to know its truth condition. The leading alternative—sometimes called semantic antirealism—holds instead that to understand a sentence is to know the conditions under which it is correctly asserted. A view of this sort assigns each declarative sentence a class of “verification conditions,” each of which must be the sort of condition a competent human being can in principle recognize as obtaining. A semantic theory constructed upon such a basis will generally fail to respect bivalence. The only notion of truth it makes available will be epistemically constrained: Truth will be identified with knowable truth, and falsity with knowable falsity. On a view of this sort we shall not be entitled to say in advance that every well-formed question must have an answer, or that every statement of the form “*p* or not-*p*” must be true. This rejection of bivalence (and the closely related law of excluded middle) is the hallmark of semantic antirealism. To suppose that the only notion of truth we possess for a region of discourse is an epistemically constrained one is to suppose that the facts in the area are (as it were) cut to fit our intellectual capacities. Conversely, to insist that bivalence

must hold regardless of our cognitive limitations is to conceive of the facts at which our thought is directed as obtaining (in one sense) independently of us.

A closely related proposal has been advanced by Hilary Putnam, (1978, 1987). Putnam identifies full-blown “metaphysical” realism directly with the view that truth is epistemically unconstrained. As Putnam frames the issue, the metaphysical realist’s characteristic thought is that an ideal theory might be false, where an ideal theory is one that satisfies perfectly every criterion we normally employ in deciding what to believe in the target area. In the scientific case, for example, an ideal theory would be one that supplies accurate predictions of experimental outcomes while simultaneously displaying every internal theoretical virtue that scientists consider in the context of theory choice: simplicity, elegance, explanatory power, “intrinsic plausibility,” and the like. It is natural to suppose that such a theory could be false. After all, the theoretical virtues that provide our only grounds for choice among empirically equivalent hypotheses seem importantly subjective. A theory that strikes us as particularly powerful because it provides informative answers to interesting questions might strike creatures with different interests as unacceptably silent on important matters; a theory that strikes us as “intrinsically plausible” might strike creatures with different histories or cultures as strange and unlikely. The thought that an ideal theory can be false thus seems a natural expression of an appropriate human modesty, according to which we can have no guarantee in advance that our contingent, biologically, and historically conditioned sense of theoretical virtue must be a reliable guide to the facts about the physical world.

Putnam rejects this natural thought. Metaphysical realism presupposes a concept of truth that is radically divorced from our notion of correct assertion. But according to Putnam such a concept is unattainable. Putnam’s case for his view, like Dummett’s, defies simple summary; but in rough outline it proceeds as follows: The only serious effort to explain an epistemically unconstrained notion of truth is a version of the correspondence theory of truth. This approach proceeds in two stages. First, subsentential expressions such as names and predicates are associated with objects and properties as their referents. Then truth as a feature of sentences is defined recursively according to a scheme well known to logicians. Putnam’s central contention is that there is no credible account of the first stage. Every attempt to explain in realist terms how a word manages to refer to one object rather than another—that is, every attempt to

explain how language “hooks on” to the world—is either plainly unsatisfactory or implies a radical indeterminacy of reference.

Putnam’s alternative is to identify truth directly with “ideal acceptability,” a position he calls internal realism. The position is realist, not simply because it is compatible with what has here been called minimal realism, but also because it eschews reductionism while remaining compatible with all of the ordinary denials of mind dependence that are part of our scientifically informed worldview. Since it is plainly correct by ordinary standards to assert that mountains exist even when no one is aware of them, the internal realist will agree that mountains do not depend in this literal sense on our thought and are therefore in that sense objective. Still, the view does imply an internal connection at the global level between the way the world is and the way we are disposed to conceive of the world in what Charles Sanders Peirce called “the ideal limit of inquiry.” According to the internal realist, we should not say (as the idealist would) that the mind somehow constructs the world but rather that “the mind and the world together make up the mind and the world” (Putnam, 1978).

It remains uncertain whether the efforts of Dummett, Putnam, and others to describe a plausible alternative to realism on the matter of objectivity can succeed. It is to be noted that the arguments they provide indict any epistemically unconstrained notion of truth whatsoever, and hence that if they succeed at all they imply a global antirealism according to which every region of human thought that satisfies the condition of minimal realism is directed at a region of fact that is somehow constituted in part by our thought about it. But this can be rather hard to believe. The difficulty emerges most dramatically when we consider discourse about the past. Most of us are inclined to believe that every (nonvague) question about the past must have an answer. There is a fact of the matter, we suppose, as to whether Genghis Khan was right-handed, even if we cannot in principle obtain any pertinent evidence. But it is likely that neither “Genghis Khan was right-handed” nor its denial is assertible. Any view according to which this implies that the statement is neither true nor false is therefore bound to strike us as initially incredible. Perhaps more important, there is reason to doubt whether a commitment to an epistemically constrained notion of truth always implies a rejection of the realist’s rhetoric of objectivity and independence. It is conceivable, for example, that a moral realist for whom the demands of morality are entirely independent of our passions and interests might nonetheless insist that the

moral facts—because they represent rationally compelling demands on human action—must be accessible in principle to human beings. Moral truth would then be epistemically constrained; and yet the realist’s rhetoric of objectivity and independence would not be undermined.

To be a realist about a region of discourse is to hold at a minimum that our core commitments in the area are largely true when interpreted “at face value.” However, this minimal characterization fails to capture the realist’s commitment to the objectivity or mind independence of his subject matter. In some cases this further commitment can be understood as the requirement that the concept of truth appropriate to the target area be epistemically unconstrained. It remains unclear, however, whether this characterization is adequate to every case. The search for a fully general account of the realist’s commitment to objectivity is perhaps the central open question in this part of philosophy.

REALISM AND NATURALISM, MATHEMATICAL

Many versions of realism in mathematics are intimately related to versions of naturalism. The purpose of this article is to explore relationships between the various views, and, briefly, the main opposition to them. The focus here is exclusively on mathematics. So, for example, “Platonism” is to be read as “Platonism about mathematics.” This entry does not claim to do justice to the subtle and detailed works of everyone who works in the philosophy of mathematics, or even everyone who defends versions of realism and/or naturalism. Instead, this entry seeks to provide a useful road map of an important part of the territory.

In broad terms, *realism* is the view that mathematics is objective: independent of the lives, customs, language, and form of life of mathematicians. This statement is deliberately indeterminate. What aspects of mathematics are being discussed? What, exactly, is it independent of? And what is it to be independent? What is it to be objective? In philosophy there is little that one can take for granted.

REALISM

There are at least two forms of realism: realism in ontology, which concerns mathematical objects, and realism in truth value, which concerns mathematical truth. *Realism in ontology* is the view that mathematical *objects*, such as numbers, sets, functions, and geometric points exist independently of the mathematician. *Prima facie*, these mathematical objects do not occupy physical space; they exist eternally and are not created or destroyed; and they do not enter into causal relationships with either each other or with physical objects. Because Platonic forms share these features, realism in ontology is sometimes called “Platonism” or, as Geoffrey Hellman (1989) dubs it, “objects Platonism.” This sort of Platonism is sometimes written with a lowercase “p,” perhaps to mark some distance from Plato. For the realist in ontology, mathematical propositions are taken at face value, as statements about mathematical objects. The theorem that 101 is a prime number just is the statement that a given object, the number 101, enjoys a certain property, primeness. The sentence “101 is a prime number” has the same logical form as “Socrates is Greek.” Most versions of realism in ontology have it that mathematical truth is necessary, in a deep metaphysical sense: If the subject matter of mathematics is as these realists say it is, then typical propositions about mathematical objects—the principles of pure mathematics, for example—do not suffer from the contingencies of science or ordinary statements about ordinary physical objects.

Probably the most difficult problems associated with realism in ontology are in epistemology (see Benacerraf 1973). The realist declares that mathematics is about a realm of *prima facie* abstract, causally inert, and eternally existing objects. How can human beings ever come to know anything about these objects? How can humans have reliable, justified beliefs about such objects? The way people come to know things about physical objects typically involves some sort of causal contact between people, the knowers, and the objects (e.g., seeing them). This is ruled out with mathematical objects. Presumably, most of the beliefs that mathematicians have about mathematical objects are true. Mathematicians are reliable indicators of how things are in the mathematical realm. How does one explain this reliability (see Field 1989, essay 7)?

One resolution to these problems is to postulate a special faculty that humans have, an intuition, that links humans to the mathematical realm. Such was Plato’s own solution to the analogous problem concerning Forms. Some of the logician Kurt Gödel’s (1944, 1964) remarks can be interpreted along these lines:

Despite their remoteness from sense experience, we do have something like a perception also of the objects of set theory, as is seen from the fact that axioms force themselves upon us as being true. I don’t see any reason why we should have less confidence in this kind of perception, i.e., in mathematical intuition, than in sense perception ... It should be noted that mathematical intuition need not be conceived of as a faculty giving an *immediate* knowledge of the objects concerned. Rather, it seems that, as in the case of physical experience, we *form* our ideas also of those objects on the basis of something else which is immediately given ... It by no means follows ... that the data of this ... kind, because they cannot be associated with actions of certain things upon our sense organs, are something purely subjective ... Rather they ... may represent an aspect of objective reality, but, as opposed to the sensations, their presence in us may be due to another kind of relationship between ourselves and reality. (Gödel 1964, p. 484)

A philosopher who is inclined this way has the task of trying to square the presence of mathematical intuition with the current scientific view of a human being as a thoroughly physical organism in a physical universe.

LOGICISM. Another strategy for epistemology comes from *logicism*, the view that mathematical truth is a species of logical truth. The epistemology for mathematics is thus the epistemology for logic. The most detailed developments are those of Gottlob Frege (1884, 1893) and Alfred North Whitehead and Bertrand Russell (1910). Of those, Frege was a realist in ontology, at least for arithmetic and analysis. So for Frege, logic has an ontology—there are “logical objects.” Numbers are constructed out of logical objects.

In attempting to define the natural numbers and the general notion of *natural number*, Frege (1884, §63) proposed the following principle, which has become known as “Hume’s principle”:

For any concepts F, G , the number of F ’s is identical to the number of G ’s if and only if F and G are equinumerous.

Two concepts are equinumerous if they can be put in one-to-one correspondence. Frege showed how to define equinumerosity without invoking natural numbers. In the end, he balked at taking Hume’s principle as the ulti-

mate foundation for arithmetic, and went on to provide an explicit definition of the natural numbers in terms of concepts and their extensions. The number two, for example, is the extension (or collection) of all concepts that hold of exactly two elements. Unfortunately, the inconsistency in Frege's theory of extensions, as shown by Russell's paradox, marked a tragic end to Frege's logicist program.

Variations of Frege's approach are vigorously pursued in the early twenty-first century, in the work of Crispin Wright, beginning with (1983), and others such as Bob Hale (1987) and Neil Tennant (1997). The idea is to bypass the treatment of extensions and to work with Hume's principle, or something like it, directly. On this *neo-Fregean* approach, Hume's principle is taken to be an explanation of the concept of "number." It is an implicit definition, true by stipulation. Frege's own technical development shows that the Peano postulates can be derived from Hume's principle in a standard, higher-order logic. Indeed, the only essential use that Frege made of extensions was to derive Hume's principle—everything else concerning numbers follows from that.

HYPOTHETICAL-DEDUCTIVE APPROACH. Another popular strategy for epistemology comes from an overarching hypothetical-deductive approach. The argument begins with the observation that virtually all of science is formulated in mathematical terms. One cannot believe in the truth of physics, say, without also accepting the mathematics that occurs in it. Thus, mathematics is confirmed to the extent that science is. In short, because mathematics is indispensable for science, and because science is well-confirmed and (approximately) true, one can conclude that mathematics is well-confirmed and true as well. This "indispensability argument" is attributed to W. W. O. Quine; a clear articulation is found in Hilary Putnam's *Philosophy of Logic* (1971, ch. 5) (see also Colyvan 2001).

STRUCTURALISM. According to *structuralism*, the subject matter of arithmetic, for example, is the pattern common to any infinite system of objects that has a distinguished initial object, which plays the role of zero, and a successor relation or operation that satisfies the induction principle. The arabic numerals exemplify this *natural number structure*, as does an infinite sequence of distinct moments of time, an infinite sequence of discrete points in space, and so on. Similarly, real analysis is about the real number structure, set theory is about the set-theoretic-hierarchy structure, and topology is about topological structures. According to the *ante rem* version

of this view, the natural number structure, for example, exists independently of whether it has instances in the physical world, or any other world for that matter (see Shapiro 1997, Resnik 1997, also Parsons 1990). This is an ontological realism. The number six, for example, is a place in the natural number structure, the seventh place (if one begins with zero). Because, on the view in question, the structure exists objectively, then so do its places. Structuralists have proposed various epistemological strategies, ranging from pattern recognition, linguistic abstraction, implicit definition (much like neo-logicism), and postulation via indispensability (with the Quinean). One line, shared with the full-blooded platonism articulated by Mark Balaguer (1998), holds that the realm of structures is so robust that every coherent axiomatization is true of at least one structure. So the sticky problem concerning knowledge of mathematical objects reduces to knowledge of the coherence of an axiomatization.

THE OPPOSITION: ANTIREALISM IN ONTOLOGY. Speaking logically, the opponents of realism in ontology fall into two camps. One group holds that numbers, functions, sets, points, and the like exist, but not objectively. Mathematical objects are not independent of the mind, language, conventions, or the form of life of the mathematician or the mathematical/scientific community. According to traditional intuitionism, for example, mathematical objects are mental constructions (e.g., Brouwer 1912, 1948; Heyting 1956). This is an idealism of sorts. Some intuitionists have explicitly Kantian roots, tying mathematical construction to the forms of pure intuition (typically of time). Another ontological antirealist view sees mathematical objects as social constructions.

The other way to reject ontological realism is to hold that there are no distinctive mathematical objects at all. There simply are no numbers, sets, functions, points, and so on. This is called *nominalism*. Again, it comes in two varieties. On one of them, mathematical assertions keep a straightforward, face-value reading. So the statement that every natural number is prime is vacuously true, because there are no natural numbers. "Seven is prime" is either false or lacks truth-value, depending on how nondenoting singular terms are handled. On this view, mathematical objects are likened to characters and objects in fiction. The sentence that seven is prime is of a piece with "Miss Marple is nosy." Of course, fictionalists do not recommend that mathematicians settle their questions via the literal, face-value reading of their assertions. Either they advert to a "truth in mathematics" akin to "truth in the story" for fiction, or else they provide some other purpose for mathematics beyond seeking mathematical truth (see

Field 1989). Fictionalism is an error-theory about mathematics.

The other variety of nominalism provides alternate, non-face-value readings of mathematics. So the statements of mathematics come out true or false, without presupposing a mathematical ontology. The modal structuralist, for example, reads a statement such as “there are infinitely many prime numbers” as “any exemplification of the natural number structure has infinitely many places, each of which satisfied the property of being prime in that structure.” Charles Chihara (1990, 2004) provides versions of various mathematical theories in terms of possible linguistic constructions. One interesting issue concerns the relationship between the “nominalized” assertions and their original counterparts (see Burgess and Rosen 1997).

REALISM IN TRUTH-VALUE. These nominalistic programs lead to another major type of realism concerning mathematics. Georg Kreisel is often cited as suggesting that the important questions in the philosophy of mathematics do not concern the existence of mathematical objects, but rather the objectivity of mathematical assertions. Let us define *realism in truth-value* to be the view that mathematical statements have objective and nonvacuous truth-values independent of the minds, languages, and conventions of mathematicians.

Once again, the opponents to this view logically fall into two categories, depending on what is being denied. The radical opposition holds that mathematical statements have no nonvacuous truth-values at all. The fictionalist, noted above, is the primary and perhaps only occupant of this category. It is difficult to conceive of a projectivism or expressivism concerning mathematics.

The less radical versions of truth-value irrealism allow that mathematical statements have truth-values, but these are not independent of the minds, languages, and conventions of mathematicians. The traditional intuitionists, as described above, fit this bill. Because, for them, mathematical objects are mental constructions, mathematical assertions relate to the activity of construction. Contemporary intuitionists, following Michael Dummett (1977, 1978) also fit this bill, holding that all truths are knowable, on broadly semantic grounds.

Realism in ontology is naturally allied with realism in truth-value. To get from the former to the latter, one just insists that the sentences of mathematics be read literally, at face value. If, for example, “seven” is a genuine singular term, and the sentence “seven is prime” is objectively true, then, it seems, “seven” denotes something, namely, the

number seven. And it exists objectively. Conversely, a realist in ontology gets to realism in truth-value by insisting that the typical propositions concerning the interrelations of the mind-independent mathematical objects are themselves objective.

Nevertheless, the connections between these realisms are not forced by logical connections that are obvious to all. As noted, many nominalists are realists in truth-value. They reject the face-value reading of mathematical assertions. At least one prominent philosopher of mathematics goes in the opposite direction. Neil Tennant (1987, 1997) holds that mathematical objects exist objectively, of necessity, and yet he adopts a Dummettian antirealism concerning truth-value.

NATURALISM

Unfortunately, the word “naturalism” has become something of a term of art, and it is hard to find a common theme that underlies every view that goes by that name. Perhaps most of them share a certain deference to the natural sciences. Quine characterizes naturalism as “the abandonment of first philosophy” and “the recognition that it is within science itself ... that reality is to be identified and described” (Quine 1981, p. 72; see also 1969). The idea is to see philosophy as continuous with the sciences, not prior to them in any epistemological or foundational sense.

QUINEAN NATURALISM. The naturalist accepts the existence of the theoretical entities, such as forces and electrons, that occur in the most up-to-date scientific theories. Current science describes the world in such terms, and it runs against the theme of naturalism to reject them on philosophical grounds, adopting some sort of instrumentalism or constructive empiricism. When it comes to mathematics, however, naturalists differ. As seen with the aforementioned indispensability argument, Quine himself accepts mathematics to the extent—but only to the extent—that it is needed in science. It is impossible to do physics, or just about any other science for that matter, without invoking real analysis. So the theorems of real analysis are confirmed to the extent that the various scientific theories are confirmed, and these theories are the best ones available. So Quine accepts the truth of real analysis. Moreover, some of the traditional, Platonic themes have naturalistic counterparts. For example, the eternity of mathematical objects corresponds to the fact that mathematical assertions are not inflected with tense.

Naturalized epistemology is the application of Quinean naturalism to the study of knowledge. The

philosopher sees the human knower as a thoroughly natural being within the physical universe. Any faculty that the philosopher invokes to explain knowledge must involve only natural processes amenable to ordinary scientific scrutiny.

This theme exacerbates the epistemic problems with realism. Platonic apprehension of a detached mathematical universe is ruled out from the start, as a nonnatural process. The challenge to the ontological realist is to show how a physical being in a physical universe can come to know about *abstracta* such as mathematical objects. There may be no refutation of realism in ontology, but there is a deep challenge to it. The advocate of indispensability cites the role of mathematics in science. The idea is that mathematics is known the same way that science is. However, it is not enough to leave it at that. The advocate of realism in ontology should delimit the exact role that mathematics plays in science. How, for example, is it possible for a casually isolated realm of abstracta to shed light on the interactions of physical matter? An answer to this would go a long way toward solving the epistemological puzzles.

Notice that, at best, the indispensability argument delivers the *truth* of the principles of real analysis. If one assumes that science is objective, then there is realism in truth-value. It is not clear that the Quinean naturalist is also committed to realism in ontology, despite Quine's own tendencies in that direction. This depends on whether naturalism requires the philosopher to accept the pronouncements of mathematical science at face value. Quine famously calls for regimentation of ordinary and scientific discourse, to clean up the ontological commitments. One can see some of the aforementioned nominalistic programs in this spirit. Some of them show (or try to show) how mathematics can be true without presupposing the existence of distinctively mathematical objects (Hellman 1989). And this truth is all that is needed in science, or so the argument goes.

Other nominalists take issue with the indispensability argument itself. They show how science could proceed without mathematics, or at least without mathematics as it is standardly understood (Field 1980, Chihara 2004). This is also perhaps in the spirit of naturalism.

Quine's own realism extends to real analysis, functional analysis, and perhaps a bit more. But it stops there. Quine does not accept the truth of the higher reaches of set theory unless and until it finds application in science. In fact, Quine goes so far as to recommend the adoption of a restrictive axiom in set theory ($V=L$), because it simplifies higher-set theory, noting that simplicity is a crite-

rium of theory acceptance in science. This is despite most set-theorists' rejection of this axiom. It is ironic that Quine, the naturalist, feels comfortable dictating something to mathematicians on philosophical grounds.

OTHER VERSIONS OF NATURALISM. Penelope Maddy's (1997) and John Burgess's and Gideon Rosen's (1997) versions of naturalism defend a deferential attitude towards mathematics much like the one Quine shows toward science. They note, first, that mathematics has its own methodology, distinct from so-called scientific method, and that this methodology has proven successful over the centuries. The success of mathematics is measured in mathematical, not scientific terms. Moreover, if mathematicians gave serious pursuit only to those branches known to have applications in natural science, much of the mathematics known in the twenty-first century would not exist, nor would the *science*. The history of science is full of cases where branches of pure mathematics eventually found application in science (see Steiner 1997). That is to say, the overall goals of the scientific enterprise have been well-served by mathematicians pursuing their own disciplines with their own methodology, ignoring science if necessary. Thus, one does not need a direct inferential link between a piece of mathematics and sensory experience before accepting the mathematics as a legitimate part of the web.

On general naturalistic grounds, Burgess and Rosen adopt a realism in ontology for mathematics. For them, the convenience of the face value reading of mathematical propositions counts in its favor. Someone who proposes a nominalistic reconstruction must defend their account on accepted scientific, or mathematical grounds. That is, they must show that the ontology-free versions of mathematics are better mathematics and/or better science. Foregoing philosophical puzzles concerning epistemology do not count. Maddy is more circumspect, arguing that naturalism does not demand a realist interpretation of mathematics.

The varieties of naturalism treated here might be dubbed *methodological* because they focus on the methods of science, adopting those to traditional philosophical questions. Nominalism, as construed here, is an expression of another, ontological variety of naturalism. The thesis is that the only things that exist are the material objects of science, and the only properties people need to consider are the material properties of those objects. Alternately, the only objects in which people are licensed to believe are those with which they causally interact. Mark Colyvan (2001, ch. 3) calls this the *eleatic*

principle. Another issue that separates naturalists—or at least philosophies that go by that name—is whether all legitimate knowledge is empirical. In the spirit of radical empiricism, in the manner of John Stuart Mill, Quine has launched a sustained attack on a priori knowledge. Not every contemporary naturalist follows suit. Bernard Linky and Edward Zalta (1995) argue that the proper interpretation of science requires a more traditional Platonism, according to which mathematical propositions are synthetic a priori. Clearly, an article such as this can do no more than scratch the surface of these rich and wonderful topics.

REASON

In English the word *reason* has long had, and still has, a large number and a wide variety of senses and uses, related to one another in ways that are often complicated and often not clear. However, there is one particular sense of the word in which it, with its synonyms or analogues in other languages, has figured prominently in philosophical controversy. This is the sense, sometimes distinguished typographically by an initial capital, in which the term is taken to designate a mental faculty or capacity—in which reason might, for example, be regarded as coordinate with, but distinguishable from, sensation, emotion, or will.

QUESTIONS TO BE EXAMINED

The question that has been chiefly debated by philosophers might be expressed succinctly, but far from clearly, as "What can reason do?" However, there has also been discussion of the question whether the faculty of reason is peculiar to humanity (and presumably to "higher" beings, if there are any), or whether its possession and exercise in some degree can also be ascribed to "lower" animals. It should perhaps be added that in recent years there has been much debate as to whether machines can, or in principle ever could, properly be said to think; for if an affirmative answer were to be given to this question, then there is a quite common sense of *reason* in which it would follow that that faculty could be exercised by a machine. Only the first of these questions is dealt with here.

The short but unclear question "What can reason do?" is peculiarly liable to give rise to theoretical dissension. The question may, however, be transformed with advantage into a question not directly about the "faculty" of reason itself but about those beings to whom this faculty is attributed. What, we may ask, are human beings in a position to do, in virtue of their possession of the faculty of reason? What, by means of reasoning, are we in a position to achieve? In this form it becomes very clear that the question raises at least two highly disputable issues. First, it is far from immediately clear what reasoning is—on what occasions, in what activities or processes, reason is exercised. And second, if we determine—probably with some degree of arbitrariness—what reasoning is, it may very well remain highly disputable whether this or that can or cannot be achieved by reasoning. One should, indeed, distinguish further at this point between two radically different kinds of dispute that may arise; if it were held that, for instance, knowledge of God cannot be

attained by reasoning, there would plainly be an important further distinction between holding this to be true in fact and true in principle. It might be maintained that the reasoning necessary for knowledge of God is, as a matter of fact, too difficult for frail and mortal human beings to manage; or it might be maintained, quite differently, that the kind of conclusion capable of being established by reasoning excludes in principle that kind, if there is any such, to which knowledge of God must belong. This sort of distinction can be seen as differentiating the positivism preached by Comte in the nineteenth century from the logical positivism of recent philosophy.

MANY SENSES OF REASON

What, then, is reason? Alternatively, what is reasoning? It seems scarcely possible to maintain that these questions can be given definite answers. The definitions, implicit or explicit, of the relevant terms that have been employed by philosophers and other writers vary widely and significantly; and while some may be judged preferable to others, or may adhere more closely than others to senses which the terms may bear in ordinary discourse, there seems to be no basis secure enough to support a pronouncement that a particular meaning, and hence a particular answer to the question, is exclusively correct. In any case, what is important to the understanding of philosophical writing on this topic is not that one should know what *reason* means but, rather, that one should discern, so far as possible, what meaning is attached to *reason* by an author.

CONTRASTS WITH OTHER TERMS

Here it seems particularly important and helpful to consider with what reason is contrasted, or from what it is distinguished. There is, for example, a large body of literature in which reason stands essentially in contrast with faith. In this context, what we can achieve by reason is taken to embrace the entire field of knowledge and inquiry in which, with varying degrees of skill and success, we produce or seek reasons for our views, proofs or evidence for our conclusions, and grounds for our opinions. This whole field is set in contrast with another, in which supposedly we may—or should or must—accept certain propositions or doctrines without any grounds but rather on authority or perhaps on unreasoned conviction.

There is another large body of literature in which reason stands in contrast with experience. In this context, what we can achieve by reason is much more narrowly circumscribed; here a distinction is being made between,

roughly, what we can discover or establish by merely sitting and thinking, and what we can discover or establish only by the use of our senses, by observation or by experiment. It will be observed that there are, corresponding to these wider and narrower senses of *reason*, also wider and narrower senses of the term *rationalist*; a rationalist in the one sense is concerned with denying or belittling the claims or the role of faith, and in the other with denying or belittling the role, in the acquisition of knowledge, of experience. There is no particular reason why one who is a rationalist in either one of these senses should be expected to be a rationalist in the other sense also; the two positions are quite independent of one another.

THE OBJECTS OF REASON

There is, then, no universally agreed or uniquely correct sense of *reason*. This is obvious enough, perhaps; but it is not unimportant. Clearly, even though philosophers may use this term in diverse senses without being wrong, the fact that they do so must, if unobserved by them or their readers, generate confusion and argument at cross purposes. Further, as was noted above, even if we avoid confusion at this point, many problems as to the “scope” or the “powers” of reason remain. They are, in fact, some of the major and central problems of philosophy.

Suppose that, following Brand Blanshard in his *Reason and Analysis*, we define *reason* as “the faculty and function of grasping necessary connections.” We may feel that this is not a very good definition, since it seems excessively restrictive. For example, a judge arguing his way to a decision, or a meteorologist setting forth his grounds for a weather forecast, would in this sense not be exercising the faculty of reason; the argument in each case is nondemonstrative—that is, it does not set out or rely on strictly necessary connections. However, waiving that point, the definition is at least a clear one. But notwithstanding its possession of the important virtue of clarity, the question of what reason can do is not thereby settled.

In order to settle this question, we must decide what necessary connections there are and in what cases or what fields there are necessary connections to be grasped; and the determination of this question raises, or might very well raise, almost every problem of philosophy. Are we to hold, with Plato, that no necessary connections are to be discerned in the everyday world, but only in an intelligible world of Forms? Or are we to hold, with David Hume and many others, that strictly necessary connections are to be found only in the formal, abstract relations between our concepts or ideas? Was Immanuel Kant right in supposing that the moral law can be demonstrated a priori,

and is therefore necessary? Or, on the contrary, was Hume correct in holding that in the field of moral judgment “reason is the slave of the passions”? Are causal relationships cases of necessary connection? Are they perhaps, as John Locke seems to have held, really cases of necessary connection that in practice, however, we are inveterately unable to grasp as such? And so on.

BASIC QUESTIONS

The point that emerges here is simply this: Whatever particular definition of the faculty of reason we may, implicitly or explicitly, adopt, it seems unavoidable that it will be attempted thereby to distinguish this faculty from others as being that by the exercise of which we can perceive, or arrive at, truths of some particular kind or kinds; and this kind of truth, or these kinds of truths, will in turn be distinguished from other kinds on logical or epistemological grounds. If so, then the question of what we can actually achieve or come to know by reason unavoidably becomes the question of what propositions are of that kind or those kinds; and this is precisely the question about which, in any field, philosophical controversy may, and characteristically does, arise. Thus the apparently simple question “What can reason do?” is not a neutral question on which otherwise dissentient philosophers may expect to be in agreement. On the contrary, it is very likely that their disagreement consists precisely in their diverse answers to this question. It may further be felt, with justice, that if this innocent-looking question unavoidably raises major philosophical issues concerning the logical and epistemological analysis and classification of propositions, it would probably be advantageous to raise those questions directly and overtly rather than as an only half-acknowledged corollary of a discussion that is ostensibly concerned with a faculty of the mind. There are few modern philosophers who would naturally cast their discussions in this latter idiom.

One final risk of confusion is worth pointing out. It is probably true that in recent philosophy there has been a persistent tendency to narrow the field in which necessities, strictly speaking, are admitted to be found; and also, perhaps more significantly, a persistent tendency to take the awesomeness out of necessity by attempts, more or less successful in various fields, to exhibit necessity as fundamentally derived from the unpuzzling, and perhaps unimposing, phenomenon of tautology. In this sense, then, it can be said that there has been some tendency both to narrow the scope conceded to reason and perhaps also to make reason itself seem less mysterious and grand. In some, this tendency has occasioned considerable

distress: As Bertrand Russell has expressed it, “My intellectual journeys have been, in some respects, disappointing.... I thought of mathematics with reverence, and suffered when [Ludwig] Wittgenstein led me to regard it as nothing but tautologies” (*The Philosophy of Bertrand Russell*, edited by P. A. Schilpp, Evanston, IL, 1946, p. 19).

EXAMINATION OF REASON’S POWERS

There are several instances in which Russell’s sense of distress has been expressed in curiously bellicose terms. Books have been written in defense of reason, and exponents of the contemporary trend have been castigated as reason’s enemies. But this latter charge, even if there is some sense in which it might be well founded, is peculiarly liable to mislead, and very commonly has misled, those who urge it. One thinks, naturally and rightly, of an enemy of reason as one who is opposed or hostile to the exercise of reason. Such a person might be, for instance, a religious bigot, fearful that reason might shake the obscure foundations of his bigotry; he might be a political or racial fanatic, hostile to the careful weighing of arguments and evidence because he is half conscious that his program or doctrine lacks reasonable grounds; or he might, less malignantly, hold some doctrine about the merits of unreflecting spontaneity, disliking the slow pace, the qualifications and hedging, of rational thought. It is obvious, however, that scarcely any philosopher is, or ever has been, an enemy of reason in this sense.

Nor, to mention a group not uncommonly arraigned on the same charge, is the psychoanalyst. It is a tenet of psychoanalytic theory that reason, the dispassionate consideration of arguments and evidence, is a less conspicuous and influential determinant of the beliefs and the conduct of men than has often been supposed, or than most people might like to admit; but the psychoanalyst does not, as would an enemy of reason, rejoice in this circumstance or seek to aggravate it. Quite the contrary: Recognizing the state of the case as being what, in the light of his evidence, he takes it to be, he deploys his art in the attempt to enable people to become more rational than they would otherwise be. He may be mistaken in his theory and unsuccessful in his practice, but in any case neither in theory nor in practice does he display the least enmity toward reason.

Somewhat similarly, the philosopher who produces an argument against high traditional claims for, or traditional characterizations of, reason is, in so doing, exercising reason to the best of his ability; nor does it occur to him to question the desirability of doing so. Thus, to dissent from rationalism as a philosophical doctrine is cer-

tainly not to disparage reason; the man who values, and shows that he values, reason is not he who merely pitches reason's claims exceptionally high but, rather, he who attempts, by painstaking reasoning, to determine how high those claims may justifiably be pitched. Philosophers, whose work consists mostly in sitting and thinking, have often enough and naturally enough been prone to estimate very highly the range and significance of the results that can thereby be achieved. However, this propensity is scarcely an indication of devotion to reason; rather, it is an indication, if of anything, of pardonable self-importance.

REDUCTION

A cursory glance at the history of science reveals a continuous succession of scientific theories of various areas or domains. For example, since ancient times theories of the cosmos have been proposed to account for the observed behavior of the heavenly bodies. The geocentric Ptolemaic theory was, for instance, succeeded by the heliocentric theory of Copernicus. Another example concerns the nature of light. Corpuscular theories were succeeded by wave theories of light. Wave theories, in turn, have been followed by the quantum theories of electromagnetic radiation.

This entry concerns the nature of certain relations that may obtain between different pairs of theories in such sequences. A radical or extreme view of those relations is that of Thomas Kuhn. Kuhn (1970) famously argues that across scientific revolutions there is a radical disconnect between theories. One can find a similar argument in Paul K. Feyerabend (1962). On such a view, no

rational relations can obtain between a theory and its predecessor. However, it is fair to say that most philosophers have held, contrary to this extreme position, that there are, indeed, interesting and contentful relations between various pairs of scientific theories. One such relationship is that of reduction. It is often claimed that successor theories reduce those that they succeed. Such a relation may involve the idea that the successor or reducing theory explains or otherwise absorbs the successful features of the reduced theory. However, getting clear about exactly how the notion of reduction should be understood has been and continues to be a difficult philosophical problem.

This entry begins with a discussion of what may be called the received view of theory reduction and examines how that view has evolved as the result of various criticisms. Work on intertheoretic relations from 1997 through 2005 is then considered.

NAGELIAN REDUCTION

The *locus classicus* for contemporary discussion is Ernest Nagel's presentation of a model for theory reduction in *The Structure of Science* (1961). Nagel takes reduction to be an explanatory relation between theories where explanation is understood to involve deductive logical relations between statements characterizing the explanans and the statement characterizing the explanandum in accordance with the Hempelian (Hempel 1965) deductive-nomological model. Nagel holds that "[r]eduction ... is the explanation of a theory or a set of experimental laws established in one area of inquiry, by a theory usually though not invariably formulated for some other domain" (1961, p. 338). The idea here is that a theory *T* reduces a theory *T'* just in case one can derive (and thereby explain) the laws of *T'* from the laws of *T*.

Nagel realizes that for some intuitive cases of theory reduction such derivations would not be immediately possible. If the vocabulary of the reduced (succeeded) theory contains terms referring to entities or properties that are not mentioned in the vocabulary of the reducing (successor) theory, then it will be impossible to derive the laws of the reduced theory containing those terms from the laws of the reducing theory. Reductions involving theories with distinct vocabularies are called heterogeneous by Nagel. By contrast, homogeneous reductions are taken by him to be rather straightforward and unproblematic.

This view of homogeneous reductions is somewhat naive. Lawrence Sklar (1967) points out that homogeneous reductions, in fact, are rare. Instead, what one has typically is the derivation of an approximation to the

reduced theory and not of the reduced theory itself. An example discussed by both Nagel and Sklar concerns the homogeneous reduction of the Galilean theory of free fall to Newtonian mechanics and gravitational theory. Sklar notes that there really is no strict derivation of the Galilean theory, although no terms appear in the Galilean theory that do not also appear in Newton's theory.

The example of a heterogeneous reduction Nagel discusses is the apparent reduction of thermodynamics to statistical mechanics. This example has become paradigmatic of intertheoretic reduction in the general philosophical literature. (In actual fact, the reduction of thermodynamics to statistical mechanics is much more complex than Nagel's discussion allows. Sklar [1993] provides a detailed discussion of various difficulties involved in the reduction of thermodynamics to statistical mechanics.) Thermodynamics contains terms referring to properties such as temperature and entropy. Such terms are completely lacking in the vocabulary of statistical mechanics. To effect the (supposed) derivational reduction, one must connect these thermodynamic terms with terms occurring in the vocabulary of statistical mechanics.

Nagel introduces two necessary formal conditions for such heterogeneous reductions:

- *Connectability*: "Assumptions of some kind must be introduced which postulate suitable relations between whatever is signified by 'A' [a term appearing in the reduced but not the reducing theory, such as 'temperature'] and traits represented by theoretical terms already present in the primary [reducing] science."
- *Derivability*: "With the help of these additional assumptions, all the laws of the secondary [reduced] science, including those containing the term 'A,' must be logically derivable from the theoretical premises and their associated coordinating definitions in the primary [reducing] discipline." (1961, pp. 353–354)

The connectability requirement is vague as it stands. What is the exact nature of the required "suitable relations"? In the literature such relations of connectability are typically called bridge laws or bridging hypotheses and their status is a matter of debate. Nagel allows that such bridge laws need not have the form of universally quantified biconditionals for theory reduction to be possible. They might, he holds, have the form of one-way conditionals. It is this possibility that renders the requirement of derivability not superfluous (Nagel 1961, p. 355

note). With the aid of bridge laws, Nagel thinks that the reducing theory would be able to fully explain the laws of the reduced theory.

However, even having universal biconditionals as bridge laws may not itself be sufficient for reduction. Many examples exist where correlatory laws may be established—where the biconditionals are true and apparently lawlike—yet, where nothing resembling reduction can take place. Sklar (1967) offers the example of the Wiedemann-Franz law expressing a correlation between the thermal conductive properties of a material and its electrical conductivity properties. Such a law does not allow one to reduce the theory of thermal conductive properties of the material to a theory of its electrical conductive properties. Something more than mere correlation is required.

That something more is usually taken to be some kind of empirically established identity claim. For example, the reduction of physical optics to the theory of electromagnetic radiation is accomplished by noting the identity of one class of entities—light waves—with (part of) another class—electromagnetic radiation. As Sklar notes, “Light waves are not correlated with electromagnetic waves, for they are electromagnetic waves. There are not two classes of entities, but only one” (1967, p.120). Another classic example is the reduction of Mendelian genetics to molecular genetics via the identification of genes with DNA molecules.

The idea that the bridge laws must express necessary identifications between entities or classes of entities has much to recommend it. However, in many cases of apparent intertheoretic reduction such identity relations are not available. In the paradigmatic case of the reduction of thermodynamics to statistical mechanics, one sees that terms such as *temperature* and *entropy*, occurring in thermodynamics but not in statistical mechanics, refer to properties possessed by thermodynamic systems. Still, it is not at all clear what properties of statistical systems can be identified with the thermodynamic properties. For example, the standard claim that temperature is just (identical to) mean molecular kinetic energy is deeply problematic. Again, see Sklar (1993) for a detailed discussion of some of these problems.

One way of emphasizing the difficulty here is in terms of questions about the meaning of terms appearing in the distinct theories. In orthodox thermodynamics, for example, the term *entropy* gets its meaning (on one view of how theoretical terms acquire meaning) at least in part by the role the term plays in the theory. (A classic presentation of orthodox thermodynamics explicitly exhibiting

the roles of the terms is by A. B. Pippard [1957].) One sees that such terms refer to unvarying and nonstatistical properties of systems. Nevertheless, in the apparent reduction of thermodynamics to statistical mechanics the concept of entropy changes to one that explicitly allows for statistical variation and fluctuation. In what sense can one identify here? Feyerabend (1962), for one, takes this to be evidence that reduction (understood as Nagelian derivation with bridge laws) must fail.

NEO-NAGELIAN REDUCTION. In contrast to Feyerabend’s (1962) pessimistic conclusion many philosophers hold that some sort of reductive relation still obtains even in the face of problems of heterogeneity. In fact, it is often noted that in the process of reducing one theory to another, the reduced theory gets emended. One sees textbooks with titles referring to statistical thermodynamics, indicating that the orthodox thermodynamic conceptions of entropy and temperature have been changed to allow for (observable and observed) fluctuations in those quantities. The explicit recognition that the reduced theory is often changed as a result of reduction or attempted reduction takes one beyond the Nagelian conception of reduction as a relatively straightforward explanatory derivation.

Kenneth Schaffner’s (1967, 1976) model of reduction deserves mention here as a sophisticated attempt to incorporate this aspect of theoretical change into a Nagelian-type framework. Schaffner explicitly includes the corrected reduced theory in the model. On this view a theory T reduces a theory T' just in case there is a corrected version of the reduced theory, T'^* such that

- (1) The primitive terms of T'^* are associated with various terms of T via bridge laws or reduction functions
- (2) T'^* is derivable from T when supplemented by these bridge laws
- (3) T'^* corrects T in that it makes more accurate predictions than does T'
- (4) T' is explained by T in that T' and T'^* are strongly analogous to one another, and T says why T' works as well as it does in its domain of validity.

It is clear that work must be done to explicate the intuitive notion of strong analogy playing a role in this model of reduction. See William C. Wimsatt (1976) for some suggestions along these lines.

OBJECTIONS TO NAGELIAN REDUCTIONS

A number of influential objections have been raised against Nagelian models of reduction. Most of these concern the possibility of providing the appropriate bridge laws. As a result they can be seen as telling also against more sophisticated models such as Schaffner's (1967, 1976). Additionally, it has been objected that even if such bridge laws can be provided, there remains an explanatory question about their status as laws. Consider the second objection first.

EXPLANATORY QUESTIONS ABOUT BRIDGE LAWS. In those cases where bridge laws express the identification of classes of entities, to ask why those bridge laws hold is to ask a question that can be trivially answered. The reason the bridge laws hold is because the entities in question are one and the same. "Why should I believe that light waves are electromagnetic radiation?" Answer: "They just are. Period, end of story." By contrast, in cases where bridge laws express some kind of (perhaps, nomologically) necessary coextensivity between properties appearing in two theories, such a question may seem legitimate and answers may be hard to come by. Jaegwon Kim (1998) forcefully argues that this poses a serious problem for Nagelian reduction understood as attempting to effect an explanatory relation among pairs of theories.

Kim discusses the attempted Nagelian reduction of psychology (the science of the mental) to physical theory, say, neurophysiology. One can suppose that one discovers empirically a nomological correlation between being in pain and having one's C-fibers firing. A statement characterizing this correlation is taken to be a bridge law necessary for Nagelian reduction. In this case it seems reasonable to ask: "Can we understand why we experience pain when our C-fibers are firing, and not when our A-fibers are firing? Can we explain why pains, not itches or tickles, correlate with C-fiber firings?" (Kim 1998, p. 95). Kim's point is that if Nagelian reduction is supposed to provide an explanation of the reduced theory in terms of the reducing theory, then surely one must demand an explanation of the bridge laws employed in the explanatory derivation. "*For it is the explanation of these bridge laws, an explanation of why there are just these mind-body correlations, that is at the heart of the demand for an explanation of mentality*" (p. 96, emphasis in the original).

MULTIPLE REALIZABILITY. A different argument due to Jerry Fodor (1974) has been used to block attempts at almost every Nagelian reduction of a given (special sci-

ence) theory to more basic (physical) theory. This argument has come to be called the multiple realization argument. It depends on the assumption that properties appearing in the special (to-be-reduced) science may have diverse and "wildly heterogeneous" realizers in the reducing physical theory. As Fodor puts it, "The problem ... has been that there is an open empirical possibility that what corresponds to the natural kind predicates of a reduced science may be a heterogeneous and unsystematic disjunction of predicates in the reducing science" (p. 108). Thus, to continue the psychology example so prevalent in the literature, pain—a property appearing in the science of psychology whose predicate (perhaps) appears in its laws—may be realized by distinct physical or neurophysiological properties in humans, in reptiles, and possibly even in inorganic robots.

This has the consequence no one neurophysiological state can be correlated or identified with the psychological property pain. In humans it may be C-fibers firing; in reptiles it may be D-fibers firing; and in robots it may be the activation of some particular integrated circuit. The heterogeneous nature of the distinct realizers also makes it unlikely that a disjunction of those realizers will be a natural kind term in the reducing theory. Given this, and if laws relate natural kinds to natural kinds, it is unlikely that there can be anything lawlike about the bridge laws. This argument has been applied to many functionally defined properties such as being a thermostat or being a heart—properties that can be realized in many different ways in different systems or organisms.

One response, due to Kim (1992), to the realization argument is to note that while the argument may block a kind of global reduction of the special science to the lower-level physical theory, it may be possible to have (local) species or structure specific reductions. Thus, for instance, one might be able to locally reduce human pain to human neurophysiology, reptilian pain to reptilian neurophysiology, and robot pain to robot neurocircuitry. Kim (1998, chapter 4) develops an alternative functional model of reduction appropriate to this response.

Another approach (Batterman 2000) asks for an account of what makes the multiple realizability possible. Typically, multiple realizability is simply assumed and applied via the multiple realization argument to block Nagelian reductions. For instance, Fodor (1974) cites it simply as an open possibility. However, it seems reasonable to ask whether one can explain, from the point of view of the supposed reducing theory, the possibility of multiple realizability. If so, this may lead to a kind of explanation without reduction. Cases where such expla-

nations are indeed possible can be found in the physics literature where attempts are made to explain surprising universal features of various systems. *Universality* means identical or similar behavior in physically distinct systems and is, therefore, a term essentially synonymous with *multiple realizability*. For details about how such an approach to multiple realizability will go, see Robert W. Batterman (2000, 2002).

REDUCTION IN THE OTHER DIRECTION

There is an interesting terminological ambiguity that infects the term *reduction* as it is typically used in the philosophical literature and as it is used in the physics literature. Philosophers will discuss the reduction of thermodynamics to statistical mechanics, the reduction of classical mechanics to quantum mechanics, and the reduction of the ray theory of light to the wave theory. The succeeded theories are all reduced to their successors. Physicists, when they talk about theory reduction at all, tend to put things the other way around. They will say that statistical mechanics reduces to thermodynamics in the limit as the number of degrees of freedom goes to infinity. They will say that quantum mechanics reduces to classical mechanics in some kind of correspondence limit. Furthermore, they will say that the wave theory reduces to the ray theory in the limit as the wavelength of light approaches zero. That there are such different senses of intertheoretic reduction was first noted by Thomas Nickles in the paper “Two Concepts of Intertheoretic Reduction” (1973).

Interestingly, the physicists’ sense of reduction appeals to limiting relations between the pair of theories and is not concerned with derivation in logical/syntactic sense that has primarily concerned philosophers following in Nagel’s footsteps. In other words, there is no explicit concern, say, with the derivation of the laws of thermodynamics from the laws of statistical mechanics. Instead, the interest is in the potential emergence of those laws as some sort of mathematical limit is asymptotically approached. Thus, while the philosophical tradition focuses on the schema according to which theory T' reduces to theory T just in case one can derive (and thereby explain) the laws of T' from the laws of T , this other sense of reduction focuses on a schema of the following form (1):

$$\lim_{\epsilon \rightarrow 0} T = T'$$

in which theory T reduces to T' in the regime where a parameter ϵ appearing in theory T takes on a limiting value. For instance, quantum mechanics contains a constant (Planck’s constant) that plays no role in classical mechanics. As a result, one may be motivated to study the limit of quantum mechanics in which Planck’s constant approaches zero. This is a kind of correspondence limit.

The two schemas are related to one another at least in the following way. Should the equality in (1) hold for two theories T and T' , then it is reasonable to expect that the laws of T' are derivable from those of T . That is to say, it is likely that one will be able to find the appropriate connections that will allow something like a Schaffner-style neo-Nagelian reduction. On the contrary, if the equality in (1) fails to obtain for the pair of theories, then such neo-Nagelian reduction will not be possible. It will be impossible to form the relevant corrected reduced theory T'^* .

One case for which the schema (1) does obtain is in the relationship between (certain aspects of) classical Newtonian mechanics (NM) and the special theory of relativity (SR). In the limit in which velocities are slow compared with the speed of light ($(v/c) \rightarrow 0$), SR reduces to NM. The limit exists and the formulas of SR smoothly (that is uniformly) approach those of NM.

However, far more often than not pairs of theories will be related to one another by so-called singular limits. Singular limits arise when the behavior as the limit is approached (no matter how small ϵ becomes) is qualitatively different from the behavior at the limit (when $\epsilon = 0$). In such cases the equality in schema (1) fails to obtain: There will be no smooth approach of the formulas of theory T to those of theory T' .

In fact, it is fair to say that for most theory pairs of interest, schema (1) will fail. Important examples include those mentioned earlier: quantum mechanics and classical mechanics; wave theory and ray theory; and statistical mechanics and thermodynamics. Certain formulas in each of these theory pairs are related by singular limits, and it is best, perhaps, to give up on speaking of reductive relations between the theories or at least between those features characterized by the singularly related formulas (see Berry 1994, 2002; Batterman 1995, 2002).

It is important to stress that if this is correct, and so physicists’ reductions are genuinely few and far between, this does not mean that there is no reason to study the singular limiting relationships between theories. In fact, the opposite is true. There is much of interest to study in the borderland between the theories. Michael V. Berry

notes the importance of the failure of reduction due to singular limiting relations between the theories, “[M]any difficulties associated with reduction arise because they involve singular limits. These singularities have both negative and positive aspects: They obstruct smooth reduction of more general theories to less general ones, but they also point to a great richness of borderland physics between theories” (2001, p. 42).

The “great richness” of this borderland is fertile ground for studying certain aspects of emergence, a philosophical topic related to the failure of reduction. Emergent phenomena are typically taken to be novel in certain respects where this novelty is often understood as resulting from the failure of the more basic theory to explain or otherwise account for the phenomena. There has been considerable interest in the controversial issues surrounding the nature and existence of emergent phenomena. Two related approaches with the same starting point—the singular nature of limiting intertheoretic relations—are examined by Batterman (2002) and Alexander Rueger (2000a, 2000b). However, another related approach can be found in the work of Hans Primas (1998). For a different, more metaphysically motivated attempt to understand emergence, see Paul Humphreys (1997). This is currently an active area of research.

REDUCTIONISM IN THE PHILOSOPHY OF MIND

See Appendix, Vol. 10

REFERENCE

“Reference” is usually conceived as the central relation between language or thought and the world. To talk or think about something is to refer to it. Twentieth-century philosophy found such relations particularly problematic. One paradigm of reference is the relation between a proper name and its bearer. On a more theoretical conception all the constituents of an utterance or thought that contribute to determining whether it is true refer to their contributions (as, for example, a predicate refers to a property). In analytic philosophy discussion of reference was dominated until the 1960s by the views of Gottlob Frege and Bertrand Russell and modifications of them (such as those by P. F. Strawson). Criticisms of assumptions common to those views then provoked a revolution in the theory of reference. The alternatives include causal and minimalist theories.

OBJECTIONS TO DESCRIPTIVISM

One model of reference is that of descriptive fit. The paradigm is a definite description (such as “the tallest tree”) that refers to whatever it accurately describes. Frege and Russell assimilated the reference of ordinary proper names to this case by supposing that speakers associate them with descriptions. Similar accounts were later given of mass terms (such as “blood”), natural-kind terms (“gorilla”), and theoretical terms in science (“inertia”). It was conceded that most terms are associated with vague and context-dependent clusters of descriptions and that reference might be to whatever they least inaccurately described, but such liberalizations did not challenge the underlying idea that descriptive fit determines reference. However, Keith Donnellan, Saul Kripke, and Hilary Putnam proposed counterexamples to that idea. Suppose, for instance, that speakers associate the name “Jonah” with the Bible story. Traditional descriptivism concludes that the sentence “Although Jonah existed, those things happened only to someone else” is untrue. For if one person satisfied the relevant descriptions, “Jonah” would refer to him. But then descriptivism proves too much, for philosophical reflection cannot show that the Bible story is not a mere legend that grew up about a real person; if those things really happened to someone else, of whom no word reached the biblical writer, the name “Jonah” would still refer to the former, not the latter. Similarly, traditional descriptivism permits someone who thinks of gorillas primarily as ferocious monkeys to conclude falsely that the sentence “Gorillas exist, but they are not ferocious monkeys” is untrue.

A second criticism was this. Say that a term *t* rigidly designates an object *x* if and only if *t* designates (refers to) *x* with respect to all possible circumstances (except perhaps for circumstances in which *x* does not exist). Most descriptions designate nonrigidly: “the tallest tree” designates one tree with respect to present circumstances, another with respect to possible circumstances in which the former is outgrown. The descriptions that traditional descriptivists associated with names were nonrigid. However, names designate rigidly: Although we can envisage circumstances in which the Danube would have been called something else instead, we are still using our name “Danube” to hypothesize circumstances involving the very same river. Thus, most descriptions do not behave like names.

The second criticism was met by a modification of descriptivism. The descriptions associated with a name were rigidified by a qualifying phrase such as “in present circumstances.” “The tallest tree in present circumstances” rigidly designates what “the tallest tree” nonrigidly designates. The first criticism is less easily met. Some descriptivists used deferential descriptions such as “the person referred to in the Bible as ‘Jonah.’” A more general strategy is to exploit the success of any rival theory of reference by building that theory into the associated descriptions. However, such moves jeopardize the connection between reference and speakers’ understanding (a connection that descriptivism was intended to secure) as the descriptions that speakers supposedly associate with names become less and less accessible to the speakers themselves.

It is in any case clear that, as Russell recognized, not all reference is purely descriptive. If the sentence “It is hot now” is uttered at different times in exactly similar circumstances, associated with exactly the same descriptions, those descriptions are not what determines that it changes its reference from one time to the other. The reference of a token of “now” is determined by the time of its production and the invariant linguistic meaning of “now,” the rule that any such token refers to the time of its production. Similarly, the presence of an object to the speaker or thinker plays an ineliminably nondescriptive role in the reference of demonstratives such as “this.”

NONDESCRIPTIVISM

THE KRIPKE-PUTNAM PICTURE. Kripke and Putnam proposed an alternative picture. Something *x* is singled out, usually demonstratively (“this river,” “this kind of animal”). A name *n*, proper or common, is conferred on *x* (“Danube,” “gorilla”). The name is passed on from one

speaker to another, the latter intending to preserve the former's reference. Such intentions are self-fulfilling: *n* continues to refer to *x*. The beliefs that speakers would express in sentences containing *n* play no role in making *n* refer to *x*, so it can turn out that most of them are false. The picture involves two kinds of deference. Synchronically, there is division of linguistic labor: Ordinary speakers defer to experts (as in deciding which animals "gorilla" refers to). Diachronically, later speakers defer to earlier ones in a historical chain. Thus, reference typically depends on both the natural environment of the initial baptism (to fix the demonstrative reference) and the social environment of the later use. An individual speaker's understanding plays only a minor role. The account may be generalized (as to many adjectives and verbs).

The picture needs qualification. Gareth Evans pointed out that a name can change its reference as a result of misidentification, even if each speaker intends to preserve reference. What matters is not just the initial baptism but subsequent interaction between word and object. Such concessions do not constitute a return to descriptivism.

CAUSAL THEORIES. The Kripke-Putnam picture is often developed into a causal theory of reference, on which for *n* to refer to *x* is for a causal chain of a special kind to connect *n* to *x*. Such a theory goes beyond the original picture in at least two ways. First, although that picture required later uses of *n* to depend causally on the initial baptism, it did not require the initial baptism to depend causally on *x*. Kripke allowed reference to be fixed descriptively (not just demonstratively), as in "I name the tallest tree 'Albie'"; he merely insisted that the description did not give the meaning of the name. There is no causal connection between the name "Albie" and the tree Albie. Second, Kripke and Putnam did not attempt to define the notions they used in causal terms; the notion of an intention to preserve reference is not obviously causal.

Causal theories are often motivated by a desire to naturalize linguistic and mentalistic phenomena by reducing them to the terms of physical science. Such theories are therefore not restricted to proper names. Causal theorists will postulate that our use of the words "tall" and "tree" is causally sensitive to tallness and trees respectively, hoping thereby to explain the reference of "Albie." One problem for causal theories is that any word is at the end of many intertwined causal chains with different beginnings. It is extremely difficult to specify in causal

terms which causal chains carry reference. For this reason, causal theories of reference remain programmatic.

DIRECT REFERENCE. Consonant with the Kripke-Putnam picture, but independent of causal theories of reference, is the theory of direct reference developed by David Kaplan. A term *t* directly refers to an object *x* in a given context if and only if the use of *t* in that context contributes nothing to what is said but *x* itself. For Kaplan, proper names, demonstratives, and indexicals such as "now" refer directly. Ruth Barcan Marcus had earlier made the similar suggestion that proper names are mere tags. The reference of a directly referential term may be determined relative to context by its context-independent linguistic meaning, as for "now"; the claim is that what "now" contributes to the proposition expressed by an utterance of "It is hot now" is not its invariant linguistic meaning but the time itself.

Although all direct reference is rigid designation, not all rigid designation is direct reference: "the square of 7" rigidly designates 49, but the reference is not direct, for the structure of the description figures in the proposition expressed by "The square of 7 is 49." On one view all genuine reference is direct, sentences of the form "The *F* is *G*" being quantified on the pattern of "Every *F* is *G*" (as Russell held); "the *F*" is neither a constituent nor a referring term.

If "Constantinople" and "Istanbul" have the same direct reference, the proposition (C) expressed by "Constantinople is crowded" is the proposition (I) expressed by "Istanbul is crowded," so believing (C) is believing (I), even if one would not express it in those words. Similarly, when a term of a directly referential type fails to refer, sentences in which it is used express no proposition. The view is anti-Fregean. In suitable contexts Frege would attribute different senses but the same reference to "Constantinople" and "Istanbul" and a sense but no reference to an empty name; for him the sense, not the reference, is part of what is said or thought. Russell held that logically proper names are directly referential but concluded that ordinary names are not logically proper. The challenge to defenders of the direct-reference view is to explain away the appearance of sameness of reference without sameness of thought and absence of reference without absence of thought, perhaps by postulating sense-like entities in the act rather than the content of thought. The theory of direct reference concerns content, not the mechanisms of reference.

MINIMALISM. Traditional theorizing about reference is ambitious; the possibility of a broad and deep theory such as it seeks has been questioned by Richard Rorty, Robert Brandom, Paul Horwich, and others. The following schema constitutes a minimal account of reference (“*a*” is replaceable by singular terms):

(R) For any *x*, “*a*” refers to *x* if and only if $x = a$.

“London” refers to London and nothing else. A minimalist account adds to (R) the claim that (R) exhausts the nature of reference.

Some qualifications are necessary. First, if anything but a singular term replaces “*a*” in (R), the result is ill formed, for only singular terms should flank the identity sign. If expressions of other syntactic categories refer, those categories will require their own schemas. The schema for predicates might be:

(R') For any *x*, “*F*” refers to *x* if and only if $x = Fness$.

Second, the notion of a singular term must be explained (can “my sake” replace “*a*”?). Third, (R) does not say which singular terms refer. When “*a*” does not refer, (R) may not express a proposition. Fourth, (R) cannot be generalized by the prefix “In all contexts”: “today” used tomorrow does not refer to today. Rather, (R) should be understood as instantiated by sentences in different contexts (for instance, uttered tomorrow with “today” for “*a*”). Fifth, when one cannot understand the term “*a*,” one cannot understand (R). Thus, one will find many instances of (R) unintelligible.

One’s grasp of the minimal theory is not a grasp of each of many propositions; it is more like one’s grasp of a general pattern of inference. For (R) the pattern is in the sentences that express the propositions, not in the propositions themselves (it is not preserved when a synonym replaces the unquoted occurrence of “*a*”). This generality does not satisfy all philosophers. Many accept the minimal theory but reject minimalism, because they postulate a deeper (for instance, causal) theory of reference that explains (R) and (R'). Although the reductionist demand for strictly necessary and sufficient conditions for reference in more fundamental terms may be overambitious, a good picture of reference might still reveal more than (R) and (R') without meeting that demand.

Timothy Williamson (1996)

REFLECTIVE EQUILIBRIUM

Reflective equilibrium is a coherence method of philosophical justification or inquiry. Nelson Goodman (1955) introduced reflective equilibrium, although not under that name, to contemporary philosophy in a discussion of deductive and inductive logic. It is arguable, however, that philosophers have employed something such as reflective equilibrium to inquire into a wide range of topics since ancient times.

Goodman maintained that we justify an inference by showing that it conforms to the rules of either deduction or induction. But for the inferences to be justified, these rules must be valid. Goodman held that we justify rules of inference by showing that they accord with judgments we make about which particular inferences are acceptable and which are unacceptable. Goodman addressed the obvious objection to such a procedure as follows:

This looks flagrantly circular. I have said that deductive inferences are justified by their conformity to valid general rules, and that general

rules are justified by their conformity to valid inferences. But this circle is a virtuous one. A rule is amended if it yields an inference we are unwilling to accept; an inference is rejected if it violates a rule we are unwilling to amend. The process of justification is the delicate one of making mutual adjustments between rules and accepted inferences; and in the agreement thus achieved lies the only justification needed for either.

(GOODMAN 1955, p. 67)

It is possible to read Goodman's proposal as purely methodological or as more epistemological. According to the epistemological reading, when we complete the process of mutual adjustment Goodman describes, thereby bringing our judgments regarding the particular inferences and the rules of inference we accept into a state of reflective equilibrium, these rules and particular judgments are by definition justified. According to this reading, being justified consists in being part of a system of beliefs, including rules and particular judgments, that has the sort of coherence that reflective equilibrium represents.

The methodological understanding of reflective equilibrium accepts that a philosophical inquiry into inductive or deductive inference is properly conducted by a process of mutual adjustment of the kind Goodman describes; it agrees that this is the best we can do in an attempt to justify the inferences we make and the rules of inference we accept. But the methodological reading is not definite about the epistemic status of the particular and general judgments we manage to bring into reflective equilibrium. It leaves open what positive epistemic status, if any, principles and judgments that are in reflective equilibrium might have. In addition, whereas the epistemological reading is committed to a coherentist account of justification, the methodological reading leaves open how best to account for the precise epistemic status (or statuses) attained by judgments that are in reflective equilibrium. Although Goodman probably intended an epistemological reading, let us adopt a methodological understanding of reflective equilibrium in order to keep as many epistemological options open as possible.

We owe the term reflective equilibrium to John Rawls (1971), who developed the method further and applied it to moral inquiry. If we think of the method as something to be applied in a stepwise fashion, which is useful even if not entirely accurate, then an inquirer, S, begins with a large set of initial moral judgments. These judgments will be intuitive for S in the sense that they are

cognitively spontaneous; they might concern propositions that are either particular or general. The first step on the road to reflective equilibrium, according to Rawls, is for S to eliminate certain initial moral judgments. For example, judgments that are not stable over time or in which S has little confidence should be dropped, as should judgments formed when S is emotionally distraught. In general, S eliminates those judgments formed in circumstances where there is some obvious reason for suspecting error. The remaining judgments will be S's considered moral judgments.

S's next task is to formulate a moral theory, that is, a set of moral principles that accounts for S's considered moral judgments. The coherence element of the method comes into play at this stage because S will grant neither considered moral judgments nor moral theory a privileged status. S will make revisions on both sides in the attempt to forge a coherent system of moral beliefs. When the emerging theory is found to conflict with central, very confidently made considered judgments, S must revise the theory. But if a well-confirmed element of the theory that is independently plausible is found to conflict with less firmly held considered judgments, then S will revise these judgments. S's decision regarding what to revise is made for each case on the basis of what seems most likely to be true or correct to S upon due consideration (there are various other ways of expressing this idea: We might, for example, say that S is to decide on the basis of S's degrees of belief or commitment or on the basis of what seems most plausible or acceptable to S).

To this point, Rawls's method corresponds with Goodman's, but Rawls does not allow S to stop here, at a point of narrow reflective equilibrium. According to Rawls, S must next consider alternatives to the moral theory that S accepts in narrow equilibrium along with philosophical arguments for and against S's own theory and the various alternatives S is considering. In his important work on reflective equilibrium, Norman Daniels (1979) argues that we can think of this as an attempt to attain coherence between the considered moral judgments and theory that S accepts in narrow reflective equilibrium and the background theories S accepts. The idea is that the philosophical arguments that S constructs will use premises drawn from among S's broader background beliefs, which might include such things as sociological views regarding the role of morality in society and philosophical or psychological theories regarding rational decision or the nature of persons.

An argument in favor of an alternative to the moral theory that S accepts in narrow reflective equilibrium that

is successful in the sense that S finds it compelling would, in effect, show that S's moral theory, considered moral judgments, and background beliefs are not coherent. As before, S is not bound to favor any type of belief when responding to such an argument; S must decide whether to revise considered moral judgments and moral theory or background beliefs on the basis of what seems most likely to be true to S after thorough reflection. When S attains a coherent system of considered moral judgments, moral theory, and background beliefs, S will have reached a state of wide reflective equilibrium.

An inquirer can certainly move from narrow to wide reflective equilibrium in the way that Daniels maintains, but this is not the only or most interesting way things can go. Consideration of alternative moral views and the relevant philosophical arguments can provide an occasion for a more radical type of revision of belief. Daniels seems to suppose that the only way in which considering alternatives to one's own view can force one to revise beliefs is by revealing that something else one believes, and believes more strongly, conflicts with one's prior view but coheres with the alternative. But it is quite clear that consideration of alternative moral and broader philosophical views can also lead one to revise beliefs in a way that is not dictated by one's prior beliefs and degrees of commitment. It is possible for an inquirer to find an alternative view attractive in its own right, even though it conflicts with everything the inquirer previously thought; and if upon reflection the inquirer finds the new alternative sufficiently attractive, he or she might well respond by accepting the alternative and revising his or her previous views.

Wide reflective equilibrium is best understood in a way that allows for this radical type of belief revision. According to this understanding, achieving wide reflective equilibrium is not simply a matter of rooting out conflicts among the beliefs one already holds and forging general principles that coherently account for one's considered moral judgments. It crucially involves exposing one's self to alternative moral and philosophical views with the knowledge that reflection upon such alternatives might lead one to make a radical break with one's previous views.

On this understanding, the ideal of wide reflective equilibrium is not defined merely as achieving coherence among all of one's beliefs: considered moral judgments, a moral theory, and background beliefs. The ideal crucially involves attaining a kind of reflective stability. Inquirers who have attained reflective equilibrium are, in effect, immune to threats from the inside and the outside. There will be no conflicts within such inquirers' systems of

belief, and in addition they can be confident that there are no alternatives to their own systems of belief that they would find more compelling than their own upon due reflection. The first sort of reflective stability is provided by reflective equilibrium on either understanding, the second only if reflective equilibrium is understood in a more radical way.

It is important to recognize that the essential feature of a belief revision that is radical, in the strict sense here at issue, is not the number or range of beliefs that are altered but rather the fact that the alteration is not continuous with the things that one previously believed. When a belief is revised in a way that is not strictly radical, the change is required in order to attain coherence among one's beliefs, and the alteration is dictated by other things that one believes more firmly than the belief that is revised. Particularly if the belief that is revised in this way concerns a general principle, the change can require revisions to a large number of other beliefs; such a revision would likely be called radical in common parlance, but it would not be radical in the strict sense.

When a change is one that counts as radical in the strict sense, the new beliefs come to seem compelling to one on their own, apart from their logical or evidential relations to one's previous beliefs. Indeed, the new belief will likely contradict things that one previously believed very strongly. Such a change may involve many beliefs or only a few. Philosophers, who might be guilty of considering such matters only abstractly, may find it difficult to accept the possibility of such radical changes in belief, but it is easy to find descriptions in novels, biographies, and autobiographies of people altering their views in ways that seem to be radical in the strict sense.

Because reflective equilibrium grants the inquirer's considered moral judgments a crucial role in inquiry, it has been widely criticized as a sophisticated version of intuitionism, making it an unreliable and extremely conservative method. Daniels (1979) sought to rebut the charge of intuitionism by arguing that reflective equilibrium is not compatible with foundationalism, which is a characteristic of intuitionism. Daniels's basic idea is that the inquirer's considered moral judgments do not function as intuitions because reflective equilibrium allows for such extensive revision of these judgments. This response seems to rely upon too narrow a conception of foundationalism; in particular, it seems to suppose that the beliefs that serve the foundational role must be identifiable in advance of inquiry and also be unrevisable, or at least relatively unrevisable.

Given these suppositions it is natural to think that if reflective equilibrium is a foundationalist method, the inquirer's initial considered moral judgments must be the foundations, and then conclude that it cannot be a foundationalist method because these judgments are subject to way too much revision. However, if one supposes instead that the foundations might emerge through a course of inquiry, it is unclear that reflective equilibrium does not constitute a version of foundationalism. During a person's inquiry there will be various relatively strongly held judgments that determine the course of the inquiry and the views the person comes to hold in reflective equilibrium. It is unlikely that all these judgments will be drawn from among the inquirer's considered moral judgments, but almost certainly many will. Others might come from among the person's background beliefs, some might concern moral principles, and perhaps some will be about which member of a conflicting set of beliefs should be revised.

But that does not really matter. The fact remains that at the end of inquiry, it will be possible to identify a set of judgments that provide a psychological basis for the rest of the beliefs the person holds in reflective equilibrium. Many, although perhaps not all, of these judgments will probably be intuitive in the sense that they are cognitively spontaneous. It is possible, therefore, that these intuitive judgments serve as an epistemological foundation for the rest of the beliefs the person holds in reflective equilibrium. It remains to be seen whether this constitutes a ground for objection to reflective equilibrium.

Reflective equilibrium fares better when it comes to the charge that it is extremely conservative. The extensive revisability of considered moral judgments may show that it can be construed as a version of intuitionism, but it surely shows that the method is not guaranteed to produce nothing more than a cleaned up, systematized version of conventional morality. The method has the potential to, and indeed is likely to, lead many inquirers to make extensive changes to their moral views. A particular inquirer might, of course, end up holding very conventional views in reflective equilibrium. Indeed, this is just what will happen if the inquirer is more strongly committed to enough elements of conventional morality than he or she is to anything that conflicts with them, and retains these commitments through the course of reflection upon alternatives to and criticisms of conventional morality. But it is not clear that a method of moral inquiry is inadequate unless it absolutely excludes this possibility.

More worrisome is a general fact illustrated by the possibility just considered: Given the right (or perhaps one should say wrong!) moral judgments and background beliefs held strongly and tenaciously enough, it would seem to be possible for an inquirer to end up holding virtually any moral view, even a bizarre or repugnant view, in reflective equilibrium. The worry is not confined to reflective equilibrium when used as a method of moral inquiry. No matter what a person might use this method to inquire about, given the right intuitive beliefs held with sufficient strength and tenacity, the person could end up holding virtually any view one could imagine in reflective equilibrium: extreme skepticism, solipsism, nihilism, anarchism, totalitarianism, atheism, or theism—you pick whatever views you think are beyond the pale. How then could anyone take reflective equilibrium to be an acceptable approach to moral inquiry, or philosophical inquiry more generally? As various critics have put the point: The method clearly leads an inquirer to the coherent position he or she finds most acceptable, the position that best preserves beliefs to which he or she is most strongly committed, but why think this position is anything more than that, in particular, why think it is true or likely to be true?

One might have once thought that this fundamental objection is really pressing only against reflective equilibrium when used to inquire into morality and other such things, where it is all too obvious that different people can hold, and hold very strongly, very different and incompatible considered judgments. One might have presumed that for such purposes as working out valid rules for deductive or inductive inferences, which is what Goodman originally proposed that the method be used for, there is no real problem because there just is not the same sort of diversity and conflict between the strongly held considered judgments of different people. But as Stephen Stich most particularly has stressed, empirical work has shown that many of the inferences ordinary people find intuitively acceptable are in fact fallacious. Hence, we can foresee that the rules of inference these people accept in reflective equilibrium will not be valid. So we cannot even trust reflective equilibrium to be an acceptable method of inquiry for those areas where it was originally proposed.

It might seem, therefore, that Rawls's early critics were right to argue that unless we can find some reason for trusting the reliability of the intuitive judgments that play such a crucial role in the method of reflective equilibrium, this method of inquiry cannot be acceptable. Daniels (1979) was perhaps right when he claimed, in response, that it is unreasonable to expect such a reason to be provided before we begin our inquiries and that

such a reason should only be expected to emerge as part of the overall system of beliefs accepted in reflective equilibrium. But surely it seems unreasonable to hope that it will ever be possible to offer even such an internal defense of reflective equilibrium as a method that is reliable for all who might employ it. Such a defense would require that all, or nearly all, inquirers employing the method converge on the same theory, and this seems rather unlikely. In addition, this sort of defense seems to underestimate the obstacles facing reflective equilibrium: It is not just that there is no reason to think the method is reliable, but also none for suspecting that it is unreliable—there are fairly strong reasons for believing that the method is unreliable, that it is not the case that a very high proportion of those who employ it will be led to accept a system of beliefs that is largely correct.

Nevertheless, it is possible to offer a defense, albeit a modest defense, of reflective equilibrium. The first step is to recognize that there are a number of different positive epistemic statuses. For simplicity, let's distinguish only two. The first is the positive epistemic status that plays the major role in distinguishing knowledge from mere true belief. This status is most commonly referred to as justification or warrant. Attempts to account for justification in terms of the reliable formation of belief have been popular and influential. Even if such attempts fail, the majority of epistemologists would still maintain that there is some sort of strong connection between justification and truth: justified beliefs must, in some sense, be likely to be true. The second positive epistemic status is the sort of subjective rationality that Richard Foley has stressed. A belief is rational in this sense when it satisfies the believer's own epistemic standards, that is, when the believer would consider the belief likely to be true after due reflection. Unlike justification, there seems no reason to suppose that beliefs that are rational in this sense are likely to be true.

Having distinguished these two positive epistemic statuses, it should be fairly clear that reflective equilibrium can, in fact, be guaranteed to lead the inquirer to hold rational beliefs. It should also be easy to see that an inquirer who deviated from reflective equilibrium would be led to hold some beliefs that are not rational because, in order to deviate, the inquirer would have to resolve some conflict by rejecting a belief that, upon reflection, the inquirer considers more likely to be true than the belief being retained. What reflective equilibrium cannot guarantee every inquirer is justified beliefs. If it followed that by employing the method of reflective equilibrium an inquirer was sure to form rational beliefs but equally

sure to form unjustified beliefs, and hence fail to attain knowledge, the method would indeed be unacceptable. But it would be hasty to infer that no inquirer employing reflective equilibrium can be led to hold justified beliefs simply because the method cannot guarantee justified beliefs to all inquirers.

In an influential paper on the method of moral inquiry written years before he advocated reflective equilibrium, Rawls (1951) argued that we should construct a moral theory by formulating principles that account for the considered moral judgments of competent moral judges. Whereas the notion of considered moral judgments is used in describing reflective equilibrium, the notion of the competent moral judge has fallen by the wayside. But suppose, as we clearly do in our ordinary lives, that some people are competent moral judges, whereas others are not. We ordinarily suppose that the intuitive moral judgments of competent moral judges are reliable. We might be wrong, and of course we might also be right, that those people who have the characteristics we commonly associate with moral competence, in fact, make a person a reliable moral judge. So let us understand competent moral judges as those whose intuitive moral judgments are reliable. The beliefs competent moral judges would hold in reflective equilibrium obviously would be reliable.

If one condition for being justified is that a person must not only be reliable, but be able to prove that he or she is, then perhaps even the beliefs held by competent moral judges in reflective equilibrium are not justified. For competent judges will not be able to prove to incompetent judges that they are reliable. But this condition for being justified is almost certainly too strong: If we were to apply it across the board, we would know little or nothing. If what is necessary for justification is only that one is reliable, not that one be able to prove that one is, then the beliefs competent moral judges hold in reflective equilibrium may, for all that has been said so far, be justified.

This is not, of course, all that we might have wanted in the way of a defense of reflective equilibrium. We cannot prove that anyone is or is not a competent judge. We cannot prove which characteristics make for competent judges and which make for incompetent judges. Perhaps there are no competent judges. Perhaps there are, but even they do not know that they are. But it is not outlandish to think that there are competent moral judges and that most of us know something about who they are and what they are like. But for the sake of this argument, suppose only that it is possible that there are competent

moral judges. If there are any competent judges, then the beliefs they hold in reflective equilibrium are justified. And this suggests that these beliefs, or at least many of them, might count as knowledge.

So we can say this much about reflective equilibrium. It is the only rational method of inquiry and it is possible that, by employing this method, a person will be led to hold justified beliefs and to attain knowledge. This is certainly less than one would like to be able to say in support of a method of philosophical inquiry, but it is sufficient to show that reflective equilibrium is an acceptable method for ethics, and philosophy more generally.

REFORMATION

In the narrower and probably most common sense, "Reformation" is the name given to the spiritual crisis of the sixteenth century that resulted in the permanent division of the Western church. The birthdate of the Reformation is traditionally given as 1517, the year in which Martin Luther posted his Ninety-five Theses on the door of the Castle Church in Wittenberg; the termination of the period may be assigned to the 1550s, by which time an ecclesiastical stalemate between the Protestants and the Roman Catholics appeared unavoidable. Sometimes the Reformation is extended backward to include such early reform movements as Lollardy or forward to include the religious conflicts, lasting into the seventeenth century, that sought to resolve the Catholic-Protestant stalemate forcibly or to readjust the divisions between the various Protestant groups. Reformation describes the aspirations of the age rather than its achievements. The Protestants did not succeed in reforming the church but only in splitting it into rival groups, each of which claimed for itself the fulfillment of the old dream of reformation in head and members.

THE AGE OF REFORMATION

The Protestant movement was not the only attempt to bring the dream into reality. It can, indeed, be correctly interpreted only in relation to other reform movements even if we determine not to include these under the same general descriptive label. The sixteenth century was the age of reformation (or of reformations, in the plural), not

just of the Reformation, and this is a fact of some importance in assessing the impact of the spiritual crisis on Western intellectual history. We should distinguish four reform groups in the sixteenth century, each of which left its own distinctive mark on Western culture.

HUMANISTIC REFORMERS. The humanists were not merely (as Luther himself thought) forerunners who prepared the way for the Protestants. They developed a reform program of their own that did not lead to the formation of independent institutions but continued, even after the appearance of Luther, to exercise influence from within both of the two main confessional groups. The foremost humanistic reformer in northern Europe was Desiderius Erasmus, who wished to purify the church by returning to its primitive sources—the New Testament and the writings of the Fathers. His “philosophy of Christ” minimized the dogmatic and the institutional and treated Christ mainly as a teacher of virtue and Christianity as an ethical affair not essentially different from the pagan philosophies. Although not less critical of ecclesiastical abuses than was Luther, Erasmus deplored any action that might disrupt the unity and peace of Christendom, and this was one of the reasons that he remained aloof from the Protestant Reformation.

RADICAL REFORMERS. “Radical reformers” is a general term for a variety of groups and individuals who felt that the Protestant leaders had not gone far enough and that reform could not be brought about without abandoning the old idea of the state church (the *corpus Christianum*). Of these radical or left-wing reformers, the Anabaptists (Swiss Brethren, Hutterites, and Mennonites) were biblical literalists who sought to establish voluntary associations of the regenerate on the New Testament pattern. The spiritualists (Andreas Carlstadt, Thomas Münzer, Sebastian Franck, Caspar Schwenckfeld), appealing to the Spirit who caused the Scriptures to be written, laid claim to immediate converse with God. The rationalists (notably the two Socinus) read the Bible in the light of reason even when reason led them to deny Christ’s full deity and atoning sacrifice. A few of the radicals (for example, the leaders of the Münster uprising in 1534) were revolutionaries who brought total destruction upon themselves; many, like Michael Servetus, were free spirits who founded no school, but the influence of others, despite brutal persecution by Roman Catholics and Protestants alike, still survives in some present-day denominations and sects.

CATHOLIC REFORMERS. The Roman Catholics rejected the Protestant reform as essentially a revolt against the church, and they sought renewal of the church by the twofold means of fostering a churchly piety and taking an official stand on the administrative and dogmatic demands of the “heretics.” Two of the greatest landmarks of the Catholic reformation were the establishment of the Jesuit order under the leadership of Ignatius Loyola and the work of the Council of Trent (1545–1563). The council, not without political and theological difficulties, sought to repudiate Protestant errors on authority, justification, and the sacraments. Yet the Tridentine fathers opposed many of the practical abuses and even theological inadequacies that had first provoked the Protestant movement. Preoccupation with Protestant errors, together with the militant campaign of suppression that followed the council, make it not inappropriate to speak of the Catholic reformation as the Counter-Reformation, though it was not merely this and had its roots in pre-Lutheran piety.

THE PROTESTANT REFORMATION. The Protestant leaders (the reformers in the narrower sense) were themselves not strictly a single group. Protestantism took three distinctive, though fundamentally related, forms.

Lutheranism, rooted in the religious struggles of Luther and his revolt against the papacy, prevailed in most of Germany and was wholly victorious in the Scandinavian countries. It was the Lutheran princes and cities represented at the Imperial Diet of Speyer in 1529 who, by making their historic protest, gave the Lutheran movement its nickname Protestantism. The classic formulation of Lutheran belief is the Augsburg Confession of 1530.

The so-called Reformed churches grew up first in Switzerland (under Huldrych Zwingli and John Calvin); won majorities in Scotland, Holland, and parts of Germany; and maintained strong pockets of influence in France, England (where they were called Presbyterians), and eastern Europe. From their beginning they were a less homogeneous group than the Lutherans and produced a variety of national confessions rather than a single statement comparable to the Lutheran Augsburg Confession. Nevertheless, the Lutheran interpretation of the Gospel exercised a decisive influence over the Reformed confessions, and though Zwingli sought to affirm his relative independence from the Germans, Calvin was one of Luther’s staunchest admirers.

The Anglican reformation proceeded slowly, largely for political reasons. The repudiation of papal authority by Henry VIII, though not intended to alter Catholic doc-

trine, left the door open to Protestant reform in the reign of his son Edward VI, and the Romanizing reaction under Mary only temporarily reversed the trend. The Thirty-nine Articles of Religion (Latin 1563, English 1571), adopted under Elizabeth I as the official doctrinal standard of the reformed Church of England, are largely a compilation of Continental Protestant ideas. Parts of the Lutheran confessions of Augsburg and Württemberg are reproduced verbatim, and the articles on predestination and the Eucharist are clearly indebted to Reformed (Calvinistic) theology.

ESSENTIAL PROTESTANT DOCTRINES

In all three of its branches the Protestant Reformation was inextricably bound up with social and political factors, so that its triumph was always, in the final analysis, contingent on governmental support. Nevertheless, it was essentially a religious movement and its theological ideas have left their mark on European intellectual history—sometimes, however, because they have been misinterpreted or interpreted too one-sidedly. Three beliefs are particularly associated with the Protestant movement: the authority of the Word, justification by faith alone, and the priesthood of all believers. These beliefs have frequently been explained as the advent of individualism in the religious sphere, as though the intention were to regard the individual as his own priest with immediate access to God, to leave him in solitude with his conscience and his Bible, or to make each man his own pope in the interpretation of Scripture.

Fundamentally, however, the original Protestant reformers were suspicious of “immediate access to God,” which they associated with the spiritualists, and they sought, rather, to replace the medieval notion of institutional means with a concept of the Christian fellowship as the locus of God’s Word. The Word of God was understood chiefly as an effective proclamation of the Gospel, based on the Scriptures, which evokes faith and sustains a fellowship of believers each of whom is priest to his brothers. The heart of this proclamation is the promise of free forgiveness (justification) through Christ, which needs only to be accepted by the faith that is awakened through the proclamation itself. We may perhaps add a fourth idea of great religious and even social consequence: vocation—that the good works required of the justified man are not so much special religious acts as the thankful performance of his calling for the good of his neighbor. These four ideas were held in common by all three Protestant groups, and their formulation may be traced to Luther himself. Characteristic differences

among the groups also developed; for example, the Reformed differed from the Lutherans, as is well known, on the manner in which the benefits of Christ’s Passion are received in the Eucharist.

THE REFORMATION AND WESTERN THOUGHT

The Reformation’s role in the making of the modern mind is a complex question that has ramifications in areas as diverse as social, economic, political, and artistic history as well as in the history of philosophy and science. Sometimes the Reformation has been represented as the great watershed between the medieval and modern worlds. This is, perhaps, partly because the individualism of Reformation thought has been overestimated and partly because certain isolated events in Luther’s life—the burning of the papal bull, the defiant stand before the Diet at Worms—have deeply impressed themselves on the German imagination. In some respects, however, the Reformation can be better understood as a late phase of medieval history than as an early stirring of the modern mind. The fundamental concerns of Luther were medieval, and it may be argued that in giving fresh vitality to religious questions he merely postponed for a while the triumph of Renaissance secularism. Moreover, though the Protestant reformers spoke ideally of a communion of saints (believers), in practice they refused to abandon the medieval concept of a Christian society (that is, an authoritarian, church-dominated society).

Unquestionably, the very existence of the Protestant churches alongside the Roman Catholic Church weakened the authoritarian ideal. But this was an accidental product of the Reformation—a consequence, indeed, of its failure rather than of its cherished principles. It was the humanistic reformers, not the Protestants, who undermined the dogmatic conception of religion, and it was the radicals who broke with the old alliance between the spiritual and secular arms of the *corpus Christianum*. Similarly, if, as has been argued, Calvinistic ideas had revolutionary economic and political consequences, this was hardly the reformer’s intention. On the other hand, the Reformation did, by its very nature, make a powerful impact on literature and music, education and scholarship; even its influence on the visual arts was not always uncreative.

REFORMATION AND SCIENCE

The chief contribution of the Reformation to the history of Western philosophy was no doubt the accidental one of helping philosophy toward autonomy by weakening

ecclesiastical domination. Attempts to establish the influence of Lutheran ideas on some of the German philosophers are often interesting but seldom of very great importance and sometimes farfetched. It might have been a service for philosophy, as it was for theology, that Luther shattered the medieval synthesis of Christianity and Aristotelianism, but the reformer's immediate successors reinstated the Greek philosopher, and the Christian faith was perilously entangled in an obsolete cosmology. (Ironically, Philipp Melanchthon repudiated Copernican astronomy on the ground that it represented merely a revival of outmoded theories that had already been rejected in the ancient world.)

Luther himself prepared the way for the conflict of theology and the modern worldview by refuting a scientific theory on theological grounds—if, indeed, the notorious passage from the *Table Talk*, “Joshua commanded the sun, not the earth, to stand still,” is authentic. Yet an open clash of science and religion was not unavoidable until post-Reformation theologians in the age of Protestant scholasticism had reaffirmed the old partnership with Aristotelianism and had come to think of the Scriptures as containing a “biblical science” that could compete with Copernican science. Luther and Calvin themselves did not accept the Ptolemaic cosmology in defiance of scientific evidence since the weight of the evidence during their lifetimes was still against Nicolas Copernicus. In principle, they were not suspicious of scientific progress. On the contrary, Luther welcomed the stirring of the new science, in which he saw a partial recovery of Adam's lost dominion over nature, and Calvin envied the astronomer's closeness to the mind of the Maker. They were both interested in the Bible not as an encyclopedia of supernaturally communicated information but as the vehicle of Christ's presence to his church in the Gospel proclamation.

Luther had grasped clearly that theological and scientific interest in nature are two distinct things. For example, from the religious viewpoint the light of the moon was for him a symbol of divine care, but he recognized that the astronomer's concern was to show how the moon's light was borrowed from the sun. Similarly, Calvin argued that biblical observations on the heavenly bodies, such as those in Genesis and the Nineteenth Psalm, are not scientific statements but homely forms of speech accommodated to the unlearned. Luther understood even better than Calvin that theology's heaven is not the same as the astronomical heavens; hence, the celebrated *Dextera Dei est ubique* (God's right hand is everywhere). Elementary though they may seem today, such

concessions and insights, had they not been neglected or expressly repudiated by Protestant orthodoxy, could have saved the Reformation churches from their warfare with science. Conversely, they might have prevented skeptics from drawing overhasty theological conclusions from natural science.

B. A. Gerrish (1967)

Bibliography updated by Tamra Frei (2005)

RÉGIS, PIERRE-SYLVAIN (1632–1707)

Pierre-Sylvain Régis was a student of the Cartesian physicist Jacques Rohault. Like Rohault, Régis expounded Cartesianism in public lectures. In 1680 François de Harlay de Champvallon, the archbishop of Paris, told Régis that King Louis XIV forbade public lectures for fear of uproar concerning the Cartesian explanation of transubstantiation. Régis continued to give private lessons, and by 1699 the conflict over Cartesianism had subsided, leading to his admission to the Academie des Sciences, along with Nicolas Malebranche, whose occasionalist philosophy was a response to problems of Cartesian dualism.

Régis's system is based on fourteen self-evident metaphysical principles derived from the *cogito* (Descartes' basic axiom: "I think, therefore I am").

- (1) All properties belong to something, that is, nothing can have no properties
- (2) All effects presuppose causes
- (3) An effect can have no more perfection than does its total cause
- (4) All changes in a subject proceed from an external cause

- (5) All modes presuppose substances in which to exist
- (6) A mode that modifies one kind of substance cannot modify any other kind of substance
- (7) All that exists is either a substance or a mode
- (8) Essences are indivisible; if anything is added to or subtracted from an essence, it is destroyed
- (9) Privations and negations are known only by their opposites
- (10) External things are known only by way of ideas; what one has no idea of is to one as though nonexistent
- (11) All ideas, to the extent that they represent properties, depend on their objects as exemplary causes
- (12) The exemplary cause of an idea contains formally all the perfections the idea represents
- (13) Facts attested by many people of diverse times, nations, and interests as known in themselves and of which one cannot suspect conspiracy to support a lie should be accepted as constant and indubitable as though one had viewed them oneself
- (14) Witness of infinitely powerful, wise, good, and truthful God should have as much persuasive force on one's mind as the most convincing reasons

The ontological principles are to the effect that whatever exists is either a substance or a modification of a substance and that modifications cannot belong to nothing. The basic epistemological principle is that external material bodies can be known only by way of representational ideas that are themselves mental modifications of the mind. The central principle is that all effects presuppose causes that must have as much or more perfection than their effects. All modifications are effects and thus are ultimately caused by a substance. All ideas (both sensory images and intelligible concepts) are also effects caused by some substance, and all of them represent the perfections of their causes. The basic problem with these assertions is that mind whose essence is active unextended thinking is essentially unlike matter whose essence is passive unthinking extension. Thus, all Cartesians must face the two questions first posed to René Descartes by Princess Elisabeth of Bohemia: Given that Cartesian mind and matter are essentially unlike one another, how can they interact causally? And how can a mind know extended matter by way of unextended sensations and ideas? Régis answers as Descartes does that one knows causal interaction takes place and God can make this hap-

pen, even if one does not understand how. The question of how mental ideas can represent material bodies that are essentially unlike mental things is also settled in the Cartesian way with the assertion that God makes it so, even if one does not understand how.

Régis maintains that his metaphysics, logic (which follows Antoine Arnauld's), and ethics (based on self-interest) are certain and complete. Physical explanations are also based on self-evident principles, but those humans give are only probable because, on the principles of Cartesian physics, several explanations are deducible for each event, and one does not know which one God chose. Régis says that the simplest is the most probable. If one had complete knowledge of the Cartesian deductive system as God does, however, one would have certain knowledge in physics, and one should keep that goal in mind. But the search must be made systematically. Régis, like Descartes, opposes "arbitrary hypotheses," explanations not deducible from self-evident principles within a system. Ad hoc explanations that are not part of a comprehensive theory are useless. Régis, like Descartes and all later Cartesians, believes the correct theory is mechanism.

The most distinctive feature of Régis's Cartesianism is his doctrine that man is a compound substance. In this union, eight conditions pertain:

- (1) The soul always has the idea of extension
- (2) Specific brain movements cause specific ideas
- (3) Animal spirits cause motions in the brain that give rise to imagination, sensation, and memory of material objects
- (4) Pleasure and pain are signs of bodies suitable and unsuitable to the human body
- (5) Man has a penchant to love or hate, and pursue or flee, the objects of pleasurable or painful ideas
- (6) Sentiments and passions lead to actions of the body toward self-preservation
- (7) The soul thinks of particular bodies only when particular brain movements occur
- (8) The union holds only so long as the body is alive and functions properly

Because ideas must have existing exemplary causes, Régis argues contrary to Descartes that one knows both the essence and existence of both mind and matter.

Man, Régis explains (as did Descartes' Dutch disciple Regius [Henry de Roy]), is an accidental union of mind or soul and body. Descartes himself adamantly opposes

this view by insisting that the union is substantial, not accidental. If the union is only accidental, this makes the mind or soul a property of the body, not a substance on equal standing with the material substance. Then when the body dies, this accidental mind or soul would disintegrate with the other bodily properties. Régis argues that in fact the soul disintegrates and the mind survives, but it cannot think temporally—because this depends on bodily motions—and instead can contemplate only itself and God.

Like Descartes, Régis shows how operations of the body take place through actions of external bodies on sense organs to cause movements in the brain. He admits that causal interaction between mind and body is inexplicable and can be accepted only on faith. It is a brute fact that because of its union with a body, a mind or soul has the idea of extension and can cause that body to move. And because of the union, distinctive brain movements always give rise in the mind to distinctive sensations and concepts of the material objects affecting the brain.

Descartes asserts that one is born with innate ideas of mind, God, and matter. But Régis says that all ideas, even of God, depend on brain movements. Thus for Régis, after separation of mind and body at death, the mind no longer has the idea of extension, and no imagination or memory of, or power over, the material world.

Régis claims that Pierre-Daniel Huet thinks Descartes is a skeptic because Huet does not distinguish methodological from real doubt. Also, Huet is wrong to argue that Descartes' explanation of transubstantiation does not preserve the body of Christ in the sacrament and to claim that because Descartes believes God has the power to do anything, one has no certain knowledge of one's world. Régis shows that Malebranche's theory of seeing all things in God requires an impossible union of man with God. Jean Du Hamel is accused of failing to see that mental ideas that do not resemble their material objects still make these objects known. Régis insists that Benedict (Baruch) de Spinoza fails to see that God is not an ordinary substance and thus confuses the material world with God.

Like Rohault, Régis insists that reason and faith do not conflict. Reason is infallible in the order of nature; faith, in the order of grace. Events in one order cannot be explained with principles of the other. Thus, Régis offers no physical explanation of transubstantiation—as do Descartes, other Cartesians, and the scholastic physicists. He argues that transubstantiation is an event not in the order of nature but in the order of grace.

REGIUS, HENRICUS (HENRI DE ROY) (1598–1679)

Regius (Henri de Roy), a Dutch academic, was a major figure in disputes over Cartesianism in Utrecht, The Netherlands, during the seventeenth century. Regius received a medical degree from the University of Padua before returning in 1638 to his hometown of Utrecht to become a professor of medicine and botany at the university. Before his appointment there he gave private lectures based on the *Dioptrics* and *Meteors*, two of the essays published with René Descartes's *Discourse on the Method* (1637). What Regius found to be particularly congenial in these texts was the proposal there that observable phenomena be explained in terms of the mechanical properties of insensible material parts.

In 1641 Regius took advantage of his good relations with the new rector of the university, Gisbertius Voetius, to obtain permission to submit for discussion various “medical disputations.” The first two disputations provide a mechanistic reinterpretation of Aristotelian notions, but in the third disputation Regius took the more aggressive tack of claiming that the union of the soul and body is not substantial, as the Aristotelians claimed, but accidental. Voetius responded with an appendix that defended Aristotelianism against the “new philosophy,” and on the advice of Descartes, Regius offered a response that suggested that the Aristotelians had difficulty avoiding atheism. In 1642 the burgomasters of Utrecht ordered the confiscation of Regius's response and endorsed a statement by the faculty that condemned the teaching of the new philosophy. Descartes intervened

by publishing attacks on Voetius in 1642 and 1644 that the burgomasters judged to be libelous. Fearful of imprisonment, Descartes sought the protection of the French ambassador, who succeeded in suppressing his arrest warrant.

To this point, Descartes had a favorable opinion of Regius. However, matters took a turn for the worse in 1645 when Regius sent Descartes a draft of his *Fundamenta physices*. Descartes was shocked by the assertion in one section of this text that it is impossible to prove that the soul is anything more than a mode of body. When Regius went ahead and published his text in 1646, Descartes denounced it in the preface to the French edition of the *Principles* (1647). A student of Regius published a broadsheet that highlighted Regius's rejection not only of a proof of immortality but also of innate ideas and the possibility of a proof of the existence of the material world. Descartes responded in 1648 with his *Notes against a Broadsheet*, and Regius replied that same year with his *Brevis explicatio mentis humanae*. Regius's text included a letter from Petrus Wassenaer defending Regius against the charge in the preface to the *Principles* that he had plagiarized portions of Descartes's unpublished treatise on animals. After Descartes's death Regius published second and third editions (1654 and 1661, respectively) of the *Fundamenta physices* with the new title *Philosophia naturalis*, in which he attempted to further defend the project of freeing mechanistic physics and physiology from dogmatic metaphysics, on which Descartes had attempted to found it. Regius's presentation there of the new science as a system of probable hypotheses is similar to the one found in the *Traité de physique* (1671) of the French physicist Jacques Rohault, perhaps the most influential defense of Cartesian physics in the century following Descartes's death.

REHMKE, JOHANNES

(1848–1930)

Johannes Rehmke, the German epistemologist, ontologist, and ethical philosopher, was born at Elmshorn in Schleswig-Holstein. He studied evangelical theology and philosophy at Kiel and Zürich from 1867 to 1871, receiving his doctorate in philosophy at Zürich in 1873. After some years as a high school teacher at St. Gallen, Rehmke was appointed unsalaried lecturer in philosophy at the University of Berlin in 1884. The following year he became professor of philosophy at the University of Greifswald, where he taught until 1921.

THEORY OF KNOWLEDGE

Rehmke did not assume the existence of two worlds: a world, only indirectly knowable, of transsubjective objects, and an immediately knowable world, with intrasubjective perceptions and the like as contents. Rather, he asserted the existence of directly knowable real objects. This epistemological monism was a consequence of his ontological dualism of two essentially different kinds of being. Physical (material) beings are spatially extended and occupy a place; mental (immaterial) beings are not extended and have no place.

The nonspatial, placeless character of consciousness conflicts with the uncritical application to the subject of such concepts as "in" and "external," as exemplified in such terms as "intrasubjective" and "transsubjective"—in other words, "immanent" and "transcendent," or "content of consciousness" and "external object." Not only does consciousness not involve the having of a content; it does not involve any kind of having by means of a relation, in any event one that presupposes the existence of at least two realities separated from one another. On the contrary, knowing without any relation between diverse things is possible from the outset, as can be seen in self-consciousness. In self-consciousness only one thing is

given, the particular knowing consciousness as knowing itself and as being known by itself. Thus, Rehmke's proposition "Knowing is having without a relation" expresses the immediacy of all knowledge, including knowledge of the so-called external world, the world of objects outside the body.

In his *Logik oder Philosophie als Wissenslehre* (Leipzig, 1918), Rehmke sought to demonstrate the importance of the general or universal for the movement of knowledge toward clarity. In accord with his proof of the immediacy of cognition, he rejected as false the notion that thinking is an internal, that is, intramental, activity and even rejected the notion of thought activity because the purported activity never produces a change in objects. Thinking is not a "doing" but a "finding." If, for example, someone makes the judgment "A boiled crayfish is red," this observation signifies that he as thinker finds anew in the object the red known before. What is thus discovered in the object is never something single, an individual being, but something repeated, a universal.

Because the universal forms part of each particular object, it is something objective. If red is found in the crayfish, the logical subject of the judgment is not simply "(boiled) crayfish," but "red boiled crayfish." Consequently, every judgment, with respect to the universal discovered in the particular object, is logically analytic. Grammatically, with regard to the joining of the linguistic signs into a sentence, it is synthetic.

In its function as predicate of a judgment, an objective universal is called a concept. Every concept is thus a universal. Because of its objectivity, the universal as concept, despite its relation to the thinking subject, cannot be merely subjective. It is equally erroneous to confuse or to equate the concept, which is always bound up with a particular word, with that word, that is, with the phonic structure as linguistic sign.

The objectivity of the universal as a possible concept reveals the error in the phrase "concept formation." A concept (for example, "tree") is not first constructed by comparing several objects (for example, pines, beeches, and alders) by means of an "internal activity" of thought. The concept is presupposed in the very selection of objects of the same kind. Concept formation is really conceptual clarification, the determination of which characteristics in union constitute a concept already given. Clarity is the guiding notion in Rehmke's logic. He claimed that, in any deepening of knowledge, the universal as logical predicate helps consciousness to obtain clarity, and ultimately unquestionable clarity.

Rehmke's conception of logic, that is, philosophy as theory of knowledge, is linked with his notion of philosophy as fundamental science, expressed in his *Philosophie als Grundwissenschaft* (Frankfurt, 1910). Both theory of knowledge and fundamental science are genuine sciences, directed toward that which is simply given, that is, toward objects regardless of their being real or unreal. They are also in equal measure philosophy because they deal with the totality of the given, in contrast with the particular sciences, each of which deals with only a particular section of the world. Theory of knowledge deals with the given as that which is thought (known); fundamental science deals with it in regard to its most universal character. But while logic presupposes the concept "universal," and each special science presupposes its own fundamental concepts, the task of philosophy as fundamental science is to elucidate without prejudice precisely the basic "that which is most universal."

THE TRADITIONAL ONTOLOGY

Theory of knowledge is not a fundamental science. Historically, it arose from an epistemological dualism, and as a consequence its form is faulty. In any case, it must presuppose the basic distinction between knower and other. Rehmke's painstaking ontological studies in *Philosophie als Grundwissenschaft* of the manifold "most universal" embrace five paired notions: (1) matter and consciousness, (2) the universal and the unique, (3) unity and simplicity, (4) the changeable and the unchangeable, (5) the real and the unreal. For Rehmke, of course, the first pair was primary. Beyond the merely negative description—immaterial, nonspatial, and place-less—the essence of the mental is completely determined by the concept of consciousness, or knowledge. Rehmke therefore opposed both materialism and idealism (spiritualism), as well as Spinozism.

Everything without exception proves to be either a unique thing (something that occurs only once, such as a unique tree) or a universal (something that is repeated, such as green or "treeness"). It follows that the unique and the universal do not exist without each other; indeed, objectively the universal belongs to the unique. Rehmke classified the unique into individuals (for example, individual trees) and units of individuals. He divided the latter into operational units (for example, an auto with a trailer) and living units (for example, a state). The universal is either a determination (such as angularity) or a relation (such as similarity). Rehmke attached great value to his recognition that many seemingly ontological con-

cepts, such as space, time, being, and value, are merely relational ones.

In connection with the third of his five pairs, unity and simplicity, Rehmke distinguished between individuals that are composed of individuals (and hence are ephemeral, passing) and individuals that are absolutely simple (and hence are everlasting). Examples of the latter are elementary particles and consciousness. Denying the theory of substance, he held that the individual is a union of its determinations (a body, for instance, is a union of size, shape, and location). He also analyzed each specific determination into determination as such (for instance, shape as such) and particularity.

Rehmke equated the fourth relationship, the changeable and the unchangeable, with the distinction between individual and universal. In this context he pointed out that the concept of change refers only to exchange of individual characteristics, with the determination as such (for instance, the shape as such) remaining the same.

Rehmke treated in detail the relationship between the real and the unreal. He defined the real as consisting in relationship of action. This enabled him to do justice to such properties of things as sweetness, which are often dismissed as merely subjective.

PSYCHOLOGY AND ETHICS

In his *Lehrbuch der Allgemeinen Psychologie* (Frankfurt, 1894), Rehmke stressed that human consciousness (mind) is a simple, immaterial individual being, in a constant unity of action with an essentially different body. Thus, man is not a "double-being" individual. There are four general characteristics of consciousness: (1) determination of objects, each one directly perceived or imagined, even though the perception is mediated by the sense organs; (2) states (conditions), for example, delight or listlessness; (3) thought—either distinguishing (being aware of the distinct) or uniting (awareness of unity); (4) the subject, the determination of which establishes at the same time the unity of the ego. These determinations are not to be construed as mental activities.

Because of its intermittent character, volition, despite its relations with the above determinations, is not one of them. Rehmke's analysis of volition aided him in his solution of the problem of free will. He separated the problem into four parts, each of which is answerable: (1) Is an act of the will prevented or not? (2) Is the volition random or conditioned? (3) Is there a genuine possibility of choice, or is the will constrained? (4) Is the volition freely self-determined or not?

Rehmke's theory of the will constitutes the background for his ethics. He distinguished five forms of ethics—four false and one genuine. The ethics of shrewdness has to do with men “for themselves.” The ethics of the unity of control expresses duty as an “ought.” The ethics of the unity of life expresses duty as a “must” and comprises the ethics of society (in which unity as “being with one another” is a means to a selfish end) and the ethics of community (in which unity as “being for one another” is an end in itself). Finally, separating the merely social from the moral proper is the ethics of selfless love of one person as such “for another,” arising from his knowledge of himself as at one with the other.

Translated by Albert E. Blumberg

REICH, WILHELM

(1897–1957)

Wilhelm Reich was an Austrian psychiatrist and social critic. After serving in the Austrian army during World

War I, Reich became a medical student. He obtained his M.D. from the University of Vienna in 1922 and worked for some time as assistant to Julius Wagner-Jauregg at the latter's psychiatric clinic. Even before his graduation Reich began practice as a psychoanalyst and soon came to occupy an influential position in the psychoanalytic movement. From 1924 to 1930 he conducted what came to be known as the Vienna Seminar for Psychoanalytic Therapy, the first organized attempt to devise a systematic and effective analytic technique.

Reich also founded and directed sex hygiene clinics among the industrial workers of Vienna and later, on a much larger scale, in Berlin and other German cities. During his years in Germany, Reich was a member of the Communist Party, and he attempted to integrate his work as a sex counselor within the broader revolutionary movement. Adolf Hitler's assumption of power forced Reich to flee to Denmark. His activities had always been viewed with suspicion by the leaders of the Communist Party, and Reich was finally expelled from the party after the publication of *Die Massenpsychologie des Faschismus* (Copenhagen, 1933), in which he repudiated the official communist theory about the nature of fascism and the factors leading to its victory in Germany. Also, by 1933 Reich's psychiatric views were so far removed from those of orthodox psychoanalysis that the Internationaler Psychoanalytischer Verlag handled and printed but did not “publish” (that is, refused its imprint to) the first edition of Reich's *Charakteranalyse*. The break with the psychoanalytic organization became official at the Lucerne conference of the International Psychoanalytic Association in 1934.

Attacks by orthodox psychiatrists made it necessary for Reich to leave Denmark for Sweden, but in Sweden too there was official hostility and suspicion. Reich therefore gladly accepted an invitation by the Norwegian psychologist and philosopher Harald Schjelderup to teach at the University of Oslo, where he also hoped to undertake various physiological experiments. Reich worked in Norway from 1934 to 1939. Among his students and patients at that time were the English educational reformer A. S. Neill, the American psychiatrist and pioneer in psychosomatic research T. B. Wolfe, and leading figures in Norwegian psychiatry, including Nic Hoel (Waal), Ola Raknes, and Odd Havrevold. The distinguished Norwegian novelist Sigurd Hoel was also closely associated with Reich at this time—in fact, he succeeded Reich as editor of the journal *Zeitschrift für politische Psychologie und Sexualökonomie*. In 1937 Reich became the victim of a campaign in sections of the Norwegian press. Although he

had a number of influential defenders and the government renewed his permit to stay in the country, he decided to move to New York City, where he resumed his psychiatric practice and trained numerous psychiatrists in the new technique that he had worked out during his stay in Scandinavia. Reich also lectured at the New School for Social Research from 1939 to 1941.

In the last years of his life Reich showed little interest in psychiatry, devoting all his energies to what he took to be his great discoveries in physics. In 1956 he was sentenced to two years' imprisonment for disobeying a government injunction. He died in Lewisburg Penitentiary in 1957. A brief account of the main events leading to Reich's imprisonment will be found in the last section of the present entry.

It will be convenient to distinguish three phases in Reich's career: (1) his work within the psychoanalytic movement, marked, however, by some significant departures from orthodox psychoanalysis—the rejection of symptom analysis in favor of what Reich called “character analysis,” the orgasm theory, and the attempt to understand the social function of sexual repression and neurosis; (2) Reich's efforts to relate neurotic attitudes to their somatic foundation and the development of what he called “character-analytic vegetotherapy”—a technique that constituted a drastic departure from all that preceded it; and (3) his theories about orgone energy—Reich's claim to have discovered a form of energy that is found in the atmosphere and also in the living organism and which can be concentrated in various ways, including the “orgone accumulator.” What Reich claimed during the third period is of no philosophical interest. If any of the assertions in question were true, they would be of great scientific interest; but, in fact, most professional physicists who have heard of the orgone theory have dismissed it as nonsense. In fairness to Reich it should be added that a really unbiased investigation of his physical theories remains to be undertaken.

We shall here be exclusively concerned with certain of the ideas advanced by Reich during the first two periods. Of interest to philosophers are Reich's views concerning the origin of religious and metaphysical needs, the relation between the individual and society and the possibility of social progress, and, above all, the implications of his psychiatry for certain aspects of the mind-body problem. It is regrettable that, partly because Reich's books and articles were not easily accessible and partly because the wild claims of his last years created widespread distrust of his entire work, the remarkable achievements of his second phase are relatively little-

known. To those who are put off by the recent metaphysical and pro-religious trends in psychiatry, as exhibited in the vogue of existentialist psychoanalysis and in the metapsychological speculations of Carl Jung and various Freudian analysts, Reich's concentration on the somatic basis of neurotic disturbances and the sexual problems and longings of human beings will come as a pleasant and refreshing change.

THERAPEUTIC INNOVATIONS

The philosophically most interesting part of Reich's work is unquestionably what he called “the breakthrough into the vegetative realm,” that is, his attempt to determine the physiological basis of neurotic phenomena. However, first we should briefly describe Reich's earlier psychiatric work. In the early 1920s Freudian psychiatrists practiced what in retrospect came to be known as “symptom analysis.” Neurotic symptoms were regarded as foreign bodies in an otherwise psychologically healthy organism; they are expressions of a repressed infantile drive that has reappeared in a disguised form. The task of therapy is to eliminate the repression: The symptom is removed by bringing the repressed part of the personality into harmony with the rest of the ego. By his own account, Reich soon became dissatisfied with this approach. The traumatic experiences leading to repression and the repressed drives were to be elucidated by means of free association and dream interpretation, but in fact only very few patients were capable of giving their associations free rein. Furthermore, Reich was critical of the superficial criteria of “cure” current at that time. Patients were considered “cured” upon the disappearance or alleviation of the symptom of which they had complained. However, Reich believed that the elimination of symptoms is quite compatible with the continuation of a character disturbance. Also, he questioned the existence of “monosymptomatic neuroses”—neuroses with only one serious symptom. “There are no neurotic symptoms,” he later observed, “without a disturbance of the total character. Neurotic symptoms are, as it were, nothing but peaks of a mountain chain representing the neurotic character” (*The Function of the Orgasm*, p. 16). It was Reich's contention that, unless the characterological basis of a symptom has been eliminated, it or some equally troublesome symptom is likely to reappear.

On the few occasions on which either Reich or his associates at the Vienna Seminar appeared to achieve impressive and lasting improvements, this was invariably the result of the release of powerful dammed-up emotions like rage and hatred. Some years earlier, while work-

ing in Wagner-Jauregg's clinic, Reich had been struck by a catatonic who suddenly abandoned his stupor. "It was one great discharge of rage and aggression," Reich writes. "After the seizure had subsided he was clear and accessible. He assured me that his explosion had been a pleasurable experience, a state of happiness. He did not remember the previous stuporous phase.... It was very impressive, and could not be explained on the basis of the psychoanalytic theory of catatonia" (*The Function of the Orgasm*, pp. 43–44). Neurotics, too, showed noticeable improvement only when, instead of merely achieving an intellectual recognition of a repression, the impulse or emotion in question could actually be experienced. Such "liberations" were, however, infrequent and, what is more, they occurred more or less accidentally. An effective therapy would have to bring them about in a controlled fashion.

THE "CHARACTER ARMOR." Something should be said at this stage about Reich's concept of the "character armor" that came to play a central role in the technique of character analysis with which he gradually replaced the technique of symptom analysis. This concept was originally introduced in connection with certain cases of compulsion neurosis. Sigmund Freud had shown that compulsion symptoms always bind anxiety. If such a symptom is disturbed, the anxiety frequently appears. It does not, however, always appear—anxiety cannot usually be released in this way either in compulsion neuroses of long standing or in cases of chronic depression. Such patients appeared quite inaccessible. "Emotionally blocked compulsive characters gave associations in great numbers freely, but there never was a trace of affect. All therapeutic efforts bounced back, as it were, from a thick, hard wall" (*The Function of the Orgasm*, p. 114). These patients were "armored" against any attack. Over the years they had developed a set of attitudes whose function was to protect the individual against external injury (such as being hurt or rejected by other human beings) and to protect him against feeling his own repressed emotions, especially (though not exclusively) various kinds of destructiveness.

Reich introduced the term *character armor* to refer to the totality of the typical or chronic attitudes of this kind characterizing a given individual. It is, writes Reich, "as if the affective personality put on an armor, a rigid shell on which the knocks from the outer world as well as the inner demands rebound. This armor makes the individual less sensitive to unpleasure, but it also reduces his libidinal and aggressive motility and, with that, his capacity for pleasure and achievement" (*Character Analysis*, p.

310). Patients who do not suffer from a severe compulsion neurosis (and indeed most people growing up in a repressive environment) also have a character armor, but in their cases it can usually be attacked or broken down more easily.

The technique used to attack the character armor emphasizes the so-called negative transference. According to Reich, every patient has a deep mistrust of the treatment and feels strong hostility to the psychiatrist. Although patients wish to be cured, they also resent any attempt to disturb their "neurotic equilibrium." It is tempting for the analyst to shy away from these negative reactions, since it takes a great deal of strength and composure to bear the often furious hatred that is released when the armor begins to "crack." Nevertheless, it is precisely this negative reaction that can and must be used as the foundation of the treatment. The patient must feel free to criticize the analyst, and any attitudes that mask his hostility have to be broken down. Reference to the case of a "passive-feminine young man with hysterical symptoms" may give some idea of what this technique is like. The patient was excessively polite and, because of his fears, extremely sly. He always yielded and produced abundant material, but without any inner conviction. "Instead of discussing this material," Reich reports,

I only kept pointing out his politeness as a defense against me and any really affective insight. As time went on, his hidden aggression appeared increasingly in his dreams. As the politeness decreased, he became offensive. In other words, *the politeness had been warding off the hatred*. I let the hatred come out fully by destroying every defense mechanism against it. The hatred up to that time had been unconscious. Hatred and politeness were antitheses, and at the same time the over-politeness was a disguised manifestation of hatred. (*The Function of the Orgasm*, p. 117)

If in this way repressed emotions are released and the patient actually experiences them, it is unnecessary to persuade him that he "really," "unconsciously" feels this or that. "The patient no longer talked about his hatred, he felt it; he could not escape it as long as his armor was being correctly taken apart" (p. 146).

The armor, according to Reich, varies from patient to patient, depending on his individual history, and the technique of destroying it has to be fitted to the individual case. The armor may be viewed as consisting of several layers. These layers, in Reich's words, "may be compared to geological or archaeological strata which,

similarly, are solidified history. A conflict which has been active at a certain period of life always leaves its trace in the character, in the form of a rigidity” (pp. 121–122). The neurosis of each patient has a specific structure that corresponds to its historical development, but in reverse order: “that which had been repressed latest in childhood was found to lie nearest the surface” (p. 121).

Anger and hate are not the only emotions bound by the character armor. Although destructiveness has to be emphasized and liberated in the early stages of the treatment, eventually genuine love and tenderness that had to be suppressed will also be released. The destructiveness, in the last resort, is “nothing but anger about frustration in general and denial of sexual gratification in particular” (p. 124). Destructive tendencies are most frequently “reactions to disappointment in love or to loss of love.” An organism that has been freed of its dammed-up destructiveness becomes once again capable of love. Reich referred to persons who are unarmored and who possess the capacity for love in the fullest sense as “genital characters”; and the goal of therapy is to change the patient’s neurotic character into a genital structure. According to Reich, the “energy” that nourishes neurotic symptoms and various destructive attitudes can be adequately discharged only in fully satisfactory sexual intercourse. A person with a genital character, unlike the neurotic, possesses “orgastic potency.” This Reich defined as “the capacity for surrender to the flow of energy in the orgasm without any inhibitions; the capacity for complete discharge of all dammed-up sexual excitation through involuntary pleasurable contractions ... free of anxiety and unpleasure and unaccompanied by phantasies” (*The Function of the Orgasm*, p. 79).

An individual with a genital character has undisturbed contact with his own drives and with his environment and, as a consequence, he has no need for any of the endless variety of substitute contacts and substitute gratifications of the neurotic individual. He, too, may not succeed in achieving a happy existence, since this depends on a great many factors, not all of which are within his control, but he will at least not be hampered in his struggle for happiness by irrational and destructive emotions or by excessive respect for the institutions of a life-denying society.

Reich vigorously repudiated the suggestion that, either in his therapy or in his social philosophy, his goal was a world “containing nothing but pleasure.” The function of the armor, he observed, is to protect against pain, and in breaking it down, Reich’s therapy aimed at reestablishing the capacity to feel pain as well as pleasure. “Plea-

sure and joie de vivre are inconceivable without fight, without painful experiences and without unpleasurable struggling with oneself” (p. 173). The goal is not a positive “hedonic balance” that, for all one can prove to the contrary, might be more effectively achieved by a life of monasticism but “full vitality in all possible situations of life.” The capacity to take happiness and to give love goes hand in hand with “the capacity of tolerating unpleasure and pain without fleeing disillusioned into a state of rigidity.”

REPRESSIONS AND CHRONIC MUSCULAR RIGIDITIES. Reich was led to his study of what he calls the “physiological anchoring” of neurotic conflicts and traumatic experiences partly as a result of his fundamentally materialistic orientation and partly because of the special attention paid in his technique of character analysis to the *manner* in which patients talked and acted. It is a mistake, he said, to regard rage and love (or any other emotion) as events “in the mind.” They *are* physiological processes, and if an emotion is repressed, there must be some physiological mechanism by whose means the energy in question is “bound.” Furthermore, Reich was convinced that if an adult’s neurotic character attitude is the result of childhood experiences, this can be so only if the person’s organism has in some way been chronically altered. The employment of “theoretical” terms such as “Id” and “unconscious” can easily lead to pseudoexplanations in this context. To say, for example, that a repressed childhood conflict exerts its influence “from the unconscious” may call attention to a suspected causal relation between the childhood experience and the present difficulties of the individual, but beyond that it simply amounts to admitting that one does not know how the influence in question is exerted. On occasions, it is true, Freud himself said as much and expressed his hope that some day explanations in terms of unconscious conflicts would be given a physiological meaning. At other times, however, Freud treated his theoretical terms as if they designated real and eternally inaccessible entities; and many of Freud’s followers, according to Reich, became metaphysicians whose theorizing was euphemistically labeled “metapsychology.”

Perhaps of greater influence than these general reflections was Reich’s interest in the “how” of the patient’s communications. The infantile structure, Reich observes in one place, is “conserved” in what an individual does as well as in the way in which he acts, talks, and thinks (*Character Analysis*, p. 188). Elsewhere Reich explains that he made himself independent of the so-called fundamental psychoanalytic rule (“to say everything that comes to

mind”), since it was impracticable with most patients, and that instead he took as “point of attack not only what the patient said, but everything he presented, particularly the manner of his communications or of his silence. Patients who kept silent were also communicating, were expressing something that gradually could be understood and handled” (*The Function of the Orgasm*, p. 145). It became increasingly evident to him, Reich adds, that “the form of behavior and communications, was much more essential than what the patient related. Words can lie. *The mode of expression never lies.*”

Special attention to the “how” of a patient’s behavior very naturally led to close observation of the changes in his organism during and after the release of repressed emotions. Reich’s earlier clinical reports already contained remarks about the awkwardness and the rigid movements of certain types of patients. However, it was not until the early 1930s that he began to elucidate the precise role played by muscular rigidities in the binding of impulses and emotions that had to be suppressed. The following extracts describing the beginning of a treatment in 1933 will perhaps convey better than any definition what Reich meant by the “physiological anchoring” of affects:

In Copenhagen in 1933, I treated a man who put up especially strong resistances against the uncovering of his passive-homosexual phantasies. This resistance was manifested in an extreme attitude of stiffness of the neck. ... After an energetic attack upon his resistance he suddenly gave in, but in a rather alarming manner. For three days, he presented severe manifestations of vegetative shock. The color of his face kept changing rapidly from white to yellow or blue; the skin was mottled and of various tints; he had severe pains in the neck and the occiput; the heartbeat was rapid; he had diarrhea, felt worn out, and seemed to have lost hold. ... *Affects had broken through somatically after the patient had yielded in a psychic defense attitude.* The stiff neck, expressing an attitude of tense masculinity, apparently had bound vegetative energies which now broke loose in an uncontrolled and disordered fashion. ... It was the musculature that served this inhibitory function. When the muscles of the neck relaxed, powerful impulses broke through, as if propelled by a spring. (*The Function of the Orgasm*, pp. 239–240)

This and other cases led Reich to a systematic study of chronic muscular rigidities and their relation to neurotic character attitudes. He reached the conclusion that “every neurotic is muscularly dystonic and every cure is directly reflected in a change of muscular habitus” (*Character Analysis*, pp. 311–312). Chronic muscular rigidities or spasms are found all over the bodies of the patients: in the forehead, around the mouth and in the chin, in the throat, the shoulders, the chest, the abdomen, the pelvis and thighs, and many other places. The rigid expression in the eyes of many patients, their chronic “stare,” is the result of a chronic rigidity in the lid muscles. The breathing of neurotic individuals is disturbed in comparison with the natural and free respiration of emotionally healthy people. Reich referred to the totality of these chronic muscular rigidities that an individual develops as the “muscular armor.”

Reich emphasized that it is muscle groups rather than individual muscles that become spastic—muscle groups which jointly serve a certain function, for example, to suppress the impulse to cry. Not only do the lower lips become tense in this event but also “the whole musculature of the mouth, the jaw and the throat; that is, all the muscles which, as a functional unit, become active in the process of crying” (*The Function of the Orgasm*, p. 269). In discussing the spasms frequently found in the mouth, chin, and neck, Reich enlarges on the tensions set up by the stifling of impulses to cry:

Many people have a mask-like facial expression. The chin is pushed forward and looks broad; the neck below the chin is “lifeless.” The lateral neck muscles which go to the breastbone stand out as thick cords; the muscles under the chin are tense. Such patients often suffer from nausea. Their voice is usually low, monotonous, “thin.” (*The Function of the Orgasm*, p. 271)

This is not the place to discuss in detail other of the typical rigidities that make up the muscular armor. The interested reader will find these described in various of the publications devoted to the new technique.

Upon discovering the muscular spasms and their relation to suppressed impulses and emotions, Reich devised various ways of attacking or “dissolving” them directly. In working on tensions in and around the eyes, for example, it is frequently possible to release a great deal of anxiety; in loosening up and encouraging the movement of certain muscles around the mouth, suppressed feelings of disgust can be liberated; by suitable work on the chin, it is possible, in Reich’s words, “to set free an unbelievable amount of anger.” Reich writes that he had

previously been able to bring about the release of repressed impulses and emotions by way of dissolving purely characterological inhibitions and attitudes. Now, however, “the break-through of biological energy was more complete, more forceful, more thoroughly experienced, and it occurred more *rapidly*. Also, it was accompanied in many patients by a spontaneous dissolution of the characterological inhibitions” (p. 241). Reich warns, however, that it is not possible to dispense with work on character attitudes. “Everyday practise soon teaches one,” he writes, “that it is not permissible to exclude one form of work at the expense of the other” (p. 293). With some patients work on the muscular rigidities will predominate from the beginning; with others, work on the character attitudes; but in all cases work on the muscular armor becomes more important in the later stages of the treatment.

MIND-BODY PROBLEM. The facts he discovered about chronic muscular rigidities and their relation to character attitudes and repressed emotions, Reich maintained, required the abandonment of the dualistic theories about body and mind tacitly or explicitly accepted by many psychologists and most psychoanalysts. It is a mistake to regard the muscular rigidity as a mere accompaniment or as an effect of the corresponding character attitude: It is “its somatic side and the basis for its continued existence” (*The Function of the Orgasm*, p. 269). The rigidity of a muscle group and the corresponding attitude serve the same function, namely, that of holding back a repressed emotion. The muscular armor and the character armor may therefore be said to be “functionally” identical. The only tenable answer to the body-mind problem, according to Reich (who quotes Julien Offray de La Mettrie as anticipating his position), is a materialistic form of the identity theory.

Reich’s identity theory is materialistic, not in the sense that introspection is regarded as illusory or as devoid of scientific value but in holding that a change in a person’s character, or indeed any change in a human being, cannot come about without appropriate physiological changes. The notion, writes Reich, that “the psychic apparatus functions by itself and influences the somatic apparatus is not in keeping with the facts” (*ibid.*, p. 313). Even an idea such as that of going to sleep will not “exert a somatic influence unless it is already the expression of a vegetative impulse” (*ibid.*). This conclusion, Reich insists, is not contradicted by the observation that a patient (or anybody) feels relieved when a previously repressed idea or impulse is allowed to become conscious. “We used to say,” writes Reich, “that it is a matter of a dis-

charge of psychic energy which previously was bound” (*Character Analysis*, p. 311).

Closer examination will show in such a case that both the tension and the relaxation are clearly observable somatic processes. What is introspectively felt as tension and as relief are in fact certain fairly typical rigidities and relaxations of muscles—in the forehead, in the eyes, and elsewhere in the body. Both Reich and his translator, T. P. Wolfe, insist that the issue between dualism and the identity theory is not merely a question of alternative languages but makes a difference to therapeutic practice and further research. Wolfe in particular claims that only a theory of “psychosomatic identity” makes sense of the vast array of facts that had accumulated in psychosomatic studies by 1940 and that only such a theory can provide a fruitful method of research (*The Function of the Orgasm*, pp. x and xiii).

There are two very different questions that may be raised about all of this. One may ask whether, granting that Reich has hit upon something interesting and important in connection with muscular rigidities, their origin, and their possible dissolution, an identity theory is the only philosophical position that can accommodate these facts. More fundamentally, one may raise the question of whether Reich’s empirical claims about the muscular armor are true in the first place.

As to the first of these questions, it should be pointed out that when Reich speaks of the “*functional* identity” of the character and the muscular armor, he does not seem to mean by “identity” anything as strong as has been claimed by philosophical defenders of the identity theory. To say that a certain character attitude and a certain muscular rigidity have the same function, for example, that of binding anxiety or anger, is not anything that a dualist is required to deny. It is certainly compatible with, but it does not by itself imply, the claim that the character attitude and the muscular rigidity are two aspects of the same phenomenon. It might be argued that Reich’s work on the connection between muscular rigidities and character attitudes, rather than proving any traditional version of the identity theory, shows the inadequacy of interactionistic forms of dualism. Interactionism, in allowing only for causal relations between physical and psychological phenomena, could not do justice to the intimate relations between muscular rigidities and character attitudes to which Reich has called attention. There is no reason to suppose, however, that a more open-minded form of dualism, which would not restrict the relations between body and mind to one simple type, could not accommodate the facts in question.

In the present entry we cannot attempt to answer the second of our two questions—whether Reich’s empirical claims about the muscular armor can in fact be sustained. Perhaps, however, it is permissible to remark, especially since this part of Reich’s work has received so much less publicity than his orgone theory, that psychiatrists and others who have some firsthand knowledge of it have generally been enthusiastic. This includes persons who have observed and treated children in the light of Reich’s account of the muscular armor. Since the process of repression as well as the process of cure would, on almost any theory, be most readily observable in children, confirmations (or disconfirmations) here would seem to be of special significance.

CULTURE, SOCIETY, AND CHARACTER STRUCTURE

CULTURE, MORALITY, AND THE DEATH INSTINCT. On the basis of both his clinical observations and his very extensive social work, Reich maintained that there is nothing more deadly than to be subjected to the moralistic and authoritarian upbringing which is or which was until very recently the lot of the great majority of children all over the world. The preaching and the antisexual moralism of the religious home and the authoritarian character of the conventional school stifle every vital impulse in the child. Insofar as traditional education is successful, it produces human beings with a craving for authority, a fear of responsibility, mystical longings, impotent rebelliousness, and pathological drives of all kinds. The “morals” fostered by religious mysticism and slavishly followed by many who no longer believe in religion “create the very perverted sexual life which it presumes to regulate moralistically; and the elimination of these ‘morals’ is the prerequisite for an elimination of that immorality which it tries in vain to fight” (*The Mass Psychology of Fascism*, p. 156).

There is nevertheless an important element of truth in the contention of conservative ideology that if one were to “eliminate morals,” the “animal instincts” would gain the upper hand, and that this would lead to social chaos. What is true in this contention is that the average person in our culture carries within himself an “unconscious inferno,” and while his perverse and destructive impulses are not in most cases adequately controlled by moral inhibitions, they would presumably dominate personal and social life to an even greater extent in the absence of moral regulations. This fact makes it clear that any transition from an authoritarian to a rational self-governing society must be gradual and cannot be accom-

plished by simply telling people, *as they now are*, to live according to their impulses. It does not, however, provide a justification for an ascetic morality or for the usual conservative theory that maintains that culture is based on sexual repression.

The conservative theorist errs in assuming that the antisocial impulses are “absolute and biologically given” (*The Sexual Revolution*, p. 20). This view is advocated not only in the writings of religious moralists and others to whom Reich contemptuously referred as “uplifters” or “guardians of the higher values” but also in many of the later writings of Freud and those of Freud’s followers who accepted the theory of the death instinct. Accordingly, Reich devoted much effort to a very detailed attack on the theory of the death instinct, especially as it is applied to human society and culture in Freud’s *Civilization and Its Discontents*.

On Freud’s view, Thanatos, or the striving for peace and extinction, is just as much biologically given as Eros, or the sexual strivings. Although the death instinct itself cannot be perceived, it manifests itself in a great many ways—in various forms of aggression, in self-destructiveness, and in the masochistic “need for punishment.” It also accounts for the resistances put up by patients against getting well. According to Reich, however, both clinical experience and observation of children show that the phenomena which supposedly prove the death instinct are “secondary formations,” the products of the neurosis, and not “primary” and “biological” like the sexual instinct or the need for food. Investigation reveals that suicide is either an unconscious revenge upon another person or a way of escaping the pressure of a situation that has become overwhelming. The neurotic fear of and concern with death that is frequently found in quite young people can in every case be reduced to a fear of catastrophe, and this, in turn, to genital anxiety. As for aggressiveness, Reich claimed that the proponents of the death instinct did not sufficiently distinguish between perfectly healthy forms and those which are sadistic and destructive. The former are intimately connected with life-affirming tendencies, and the latter are always reactions of the organism to the denial of the gratification of a vital need.

Reich equally denied that there is any evidence whatsoever for the theory of “primary masochism.” All clinical observations support Freud’s earlier theory that patients “had come to grief as a result of their *fear* of punishment for sexual behavior and not as a result of any *desire* to be punished for it” (*The Function of the Orgasm*, pp. 103–104). The theory of the death instinct, furthermore,

is therapeutically sterile and offers an excellent excuse for one's inability to handle a difficult resistance. In addition to providing an alibi for therapeutic failures, it serves the same function as the discredited biologicistic theory of congenital criminality or the view of Magnus Hirschfeld that exhibitionism is due to special "exhibitionistic hormones": All such views shift problems from the social to the biological realm, where nothing can—and need—be done about them.

Conservative theorists who maintain that there is an antithesis between sexuality and work fail to distinguish between "compulsive-unpleasurable" work, which is indeed regarded as a burdensome duty, and "natural joyful work," which frequently requires discipline but which is nevertheless a pleasurable gratification of a need. Reich regards as especially significant his observations on patients who achieved sexual happiness. He reports that those who, because of neurotic disturbances, had not been working, began to feel a strong need for some vital work. Those who had been engaged in work that was intrinsically interesting now blossomed and gave full rein to their talents. In some cases, however, there was a complete breakdown of work. This at first seemed to confirm the view of the antisexual moralists, but closer inspection showed that these people had previously been driven by a compulsive sense of duty and that what they rebelled against was empty and mechanical work, and not work as such. Their aversion was to pleasureless work, and their impulses were by no means antisocial. Just as society rewards some highly antisocial activities with fame and honor, Reich remarks, so "there are highly valuable, even culturally important traits and impulses which have to be repressed for considerations of material survival" (*The Function of the Orgasm*, p. 150). If there were more human beings with a genital character, this would not result in the end of "civilization," but it would in all probability lead to radical changes in the ways in which the world's work is done.

Reich concluded that civilization and culture do not depend on instinctual repression. If authoritarian education were abolished and if children grew up in a sex-affirmative environment, people would be more, and not less, peaceful and cooperative. Some types of work, namely, those in which only a person with a compulsive character can take any interest, would indeed suffer, but the arts and sciences would in all likelihood flourish as never before. Reich was not an irrationalist in any sense of the word, and like Freud he favored "the primacy of the intellect," adding, however, that the full utilization of a person's intellectual capacities presupposes "an orderly libido

economy." "Genital and intellectual primacy have the same mutual relationship as have sexual stasis and neurosis, guilt feelings and religion, hysteria and superstition" (*Character Analysis*, p. 170).

SOCIETY AND CHARACTER STRUCTURE. Freudian social theory, insofar as it existed at all when Reich began his elaborate critique of what he called "authoritarian" society, was vitiated by its "biologism" as well as its "psychological atomism," or, as Reich also called it, a "feudal individualistic psychology." By "biologism" Reich meant the tendency to treat as universal and biologically inevitable attitudes and impulses that were determined by cultural conditions. When he spoke of Freud's "psychological atomism," Reich referred to the tendency to treat individual patients and their families in isolation from the social environment that had in fact a great deal to do with their tribulations.

Rejecting Freud's biologism and accepting the early Freudian view that neurosis is basically the result of the conflict between instinctual needs and the reality which frustrates them, Reich naturally asked whether and how this frustrating reality could be significantly altered. His work at the sex hygiene clinics, furthermore, had convinced him that neuroses were by no means the fads of middle-class women who did not know what to do with their time but were emotionally crippling illnesses of almost epidemic proportions. Contrary to the assertions of the more doctrinaire and narrow-minded Marxists, there could be no doubt in Reich's view that "sexual repression, biological rigidity, moralism and puritanism are ubiquitous" and not confined to certain classes or groups of the population (*The Function of the Orgasm*, p. xxiii). The vast majority of people suffering from psychological disturbances cannot, however, be reached by individual therapy, disregarding here all the difficulties and limitations of such therapy when it is available.

If one is to do anything about this deplorable state of affairs, one must first achieve an understanding of the precise relations between society and the individual and, more specifically, between social institutions and neurotic disturbances. "Society," Reich writes, "is not the result of a certain psychic structure, but the reverse is true: character structure is the result of a certain society" ("Character and Society," p. 254). The ideology of a given society can anchor itself only in a certain character structure, and the institutions of the society serve the function of producing this character structure. If, as in all authoritarian societies, a minority holds economic and political power, it also has the power to form ideology and structure. As a

consequence, in authoritarian society, the thinking and the structure of the majority of people “corresponds to the interests of the political and economic rulers” (*The Sexual Revolution*, p. xx). The majority of human beings (Reich is writing in 1936) are “suppressed and exploited and spend most of their working hours doing monotonous and mechanical labor which they cannot help regarding as a loathsome duty.” How is it possible that “people can bear it, that they are unable to change it, that they seem to endure in silence the suffering it imposes on them?” (“Character and Society,” p. 252). They can bear their fate because the ruling economic system is “anchored in the psychic structure of the very people who are suppressed” (*People in Trouble*, p. 100).

The most important structure-forming institutions in authoritarian society are the authoritarian family, the authoritarian school, and religion. “From infancy on,” writes Reich, “people are trained to be falsely modest, self-effacing and mechanically obedient, trained to suppress their natural instinctual energies” (“Character and Society,” p. 252). In this way children become subservient to their parents and people in general “subservient to the authoritarian state power and capitalistic exploitation” (*People in Trouble*, p. 99). The most powerful instrument in achieving this mass structure is sexual repression, which is fostered in the home, in the school, and above all through the influence of religious moralism. The major mechanisms of sexual suppression in Christian countries are the prohibition of infantile masturbation, the prevention of sexual gratification in adolescence, and the institution of compulsorily lifelong monogamy, accompanied by the belief that the function of sexuality is procreation rather than pleasure. The parents who punish children for masturbating and who do their best to prevent adolescents from having a full sex life are unwittingly carrying out the purpose of the ruling powers.

There is something plausible about Reich’s contention that an atomistic psychology, no matter how correctly it may determine the causes of mental health and illness, will not by itself explain why various institutions that are plainly inimical to life and happiness nevertheless flourish and receive the support of all the major official and unofficial agencies of society. However, it is not entirely clear what he means by his claim that character structure is the result of social structure and, more specifically, that the “function” of sex-denying institutions is to make the masses helpless and dependent. Although he occasionally uses the word *purpose*, Reich is presumably asserting the existence of a “latent” rather than a “manifest” function, to use the terminology introduced by R. K.

Merton. While it may be plausibly argued that some rulers, like Joseph Stalin and certain church figures, have been aware of the connection between sexual suppression and such “desirable” traits as obedience and uncritical acceptance of the status quo, it would be farfetched to hold that either in capitalistic or in other societies the ruling circles deliberately support sex-denying institutions in order to perpetuate their power and privileges. But if the rulers are not conscious of the causal connection between sexual suppression and the submissive traits it produces, in what sense is a reference to their interest an explanation of the institutions in question? It is tempting to speak here of an “unconscious knowledge” or “unconscious realization” that sexual suppression produces submissiveness, but it is far from clear what these expressions would mean.

Reich’s views about the relation between the ideology that prevails in a society and the interests of the holders of power has obvious affinities with Marxism, and in fact a number of Marxist writers of the late 1920s and early 1930s hailed his account of the social function of sexual repression as a valuable supplement to historical materialism. However, the most influential Marxist ideologists, socialist as well as communist, rejected Reich’s account and also strongly opposed his work in his sex hygiene clinics. In his turn, Reich repudiated what he called the “economism” of Marxist theory as emphatically as he attacked the atomism of psychoanalysis. “Marxists again and again argued,” he recalls, “that the sexual etiology of the neuroses was a bourgeois fancy idea, that only ‘material want’ caused neuroses ... as if the sexual want were not a ‘material’ one: It was not the ‘material want’ in the sense of the Marxian theorists that caused the neuroses, but the neuroses of these people robbed them of their ability to do anything sensible about their needs, actually to do something constructive about their situation, to stand the competition on the labor market, to get together with others in similar social circumstances, to keep a cool head to think things out.” (*The Function of the Orgasm*, pp. 56–57).

Moreover, just as it is wrong to think that neuroses are (except very indirectly) caused by economic hardships, so it is a mistake to suppose that the social and political actions of the working classes can be predicted on the basis of their economic interests alone. Factors such as mystical and sexual longings and perverse sadistic fantasies may exert very powerful influences, as Hitler, unlike the communist, socialist, and liberal politicians, understood only too well. Fascism, to take but one example, is very incompletely characterized as a movement

engineered by capitalists to prevent the establishment of socialism. At least the German variety of fascism differed from other reactionary movements in that it was “supported and championed by masses of people” (*The Mass Psychology of Fascism*, p. ix). Marxist theory, which assumes that with few exceptions the underprivileged will be guided by their rational economic interests, is incapable of accounting for such a phenomenon.

THE STRUGGLE AGAINST RELIGION

MYSTICAL FEELINGS AND SEXUAL INHIBITIONS. According to Reich, both Karl Marx and Freud made significant contributions to our understanding of religion. Patriarchal religions are always politically reactionary, and Marxists are perfectly right in pointing out that “in every class society they are in the service of the powers that be” (p. 124). Freud, too, was correct in his view that the idea of God derives from the idea of the father and, more generally, that “the psychic contents of religion stem from the infantile family situation” (ibid.). Granting all of this, there remains a question that is not answered by the Marxist or the Freudian account, or by any of the great eighteenth-century critics of religion. Indeed, it is a question that most of these writers did not even raise but which must be asked and answered if one is to have an adequate comprehension of religion. How are we to account for the fact that “religious ideas are invested with such intense feelings”? What explains the “enormous emotional power of mysticism” (p. 122)? Or, using Reich’s favorite terminology, what is the “energy” that enables religions to gain such a firm hold on people? What is it that compels human beings not only to accept the idea of a pleasure-prohibiting, all-seeing God and the ideologies of sin and punishment, and “not to feel them as a burden but, on the contrary, to uphold and fervently defend them, at the sacrifice of their most primitive life interests?” (*The Mass Psychology of Facism*, p. 124).

Reich is strongly opposed to the tendency of “emancipated” unbelievers to dismiss religions as nothing more than the fancies of silly and ignorant people. He insists that a study of religious people—of the content of their emotions and beliefs, of the ways in which these are implanted, and of the function that they fulfill in their psychological economy—is highly rewarding. It sheds light on many other phenomena, including, for example, the psychological basis of fascism and of reactionary political movements. Such a study also explains why, by and large, free-thought propaganda is so unsuccessful in spite of the fact that from a purely rational point of view the positions defended by freethinkers are vastly superior

to the religious claims—something that is not altogether unknown among believers. Above all, a happy life for the majority of humankind is impossible unless the power of religion is broken, unless one can prevent “the mystical infestation of the masses” (p. 161).

However, in order to be effective in “the relentless fight against mysticism,” one must have a full comprehension of its origin and its psychological sources of strength so that one can meet its “artful apparatus . . . with adequate counter-measures” (p. 152). To suppose that mystical attitudes become anchored in human beings simply as a result of intellectual indoctrination is a naive and dangerous mistake. It should be noted that Reich sharply distinguishes mysticism from primitive animism. The latter is best regarded as bad science. Reich does not offer an explicit definition of “mysticism,” but it seems clear from his various writings on the subject that mysticism in the “strict and wider sense” is characterized by the belief (or feeling) that the ordinary world of physical objects and human emotions is *not enough* and the related view that there are some grand truths which human beings can come to know by nonscientific or superscientific means. Various nontheological systems of metaphysics and ontology, as well as the standpoint of those who deny that psychology can properly be a natural science (Reich is specially scathing in his comments about Ludwig Klages and Karl Jaspers), are treated by him as forms of mysticism.

The most basic feature of what Reich variously calls “religious excitations” or “mystical feelings” is that they are “at one and the same time *anti*-sexual and a *substitute* for sexuality” (p. 125). Reich claims that this conclusion is borne out by the close observation of genuinely religious people (as contrasted with those who merely pretend belief for purposes of personal gain and advancement); by character-analytic treatment of religious individuals and patients having mystical feelings of any kind; by observation of children, especially those suffering from prayer compulsions; by the writings of the mystics themselves; and also by what is known about the changes that occurred when social organization passed from matriarchy to patriarchy and class society.

Biologically, the religious individual is subject to states of sexual tension like any other living being. However, as a consequence of his sex-negating upbringing and especially his fear of punishment, he has lost the capacity for normal sexual stimulation and gratification. The result of this is that he suffers from a chronic state of excessive somatic excitation. The more thorough his religious education has been, the more it appears to him that

happiness is not attainable for him in this world and, in the long run, it does not even seem desirable any more. However, he remains a biological organism and hence cannot completely renounce the goals of “happiness, relaxation and satisfaction.” In these circumstances all he can do is seek “the *illusory* happiness provided by the religious *forepleasure* excitations” (*The Mass Psychology of Fascism*, p. 126).

The “somatic suffering” of the religious person creates in him the need for consolation and help from outside himself, particularly in his fight against what he terms the “evil instincts,” which in turn are identified with the “evils of the flesh.” His religious ideas enable him to attain a state of “vegetative excitation which resembles gratification but does not, in reality, bring about somatic relaxation” (p. 127). Not even religious ecstasies bring about anything comparable to the orgasmic relief of a satisfying sexual experience. What the religious person calls his longing for “delivery from sin” is in fact a longing for relief from sexual tension. To people who cannot achieve sexual gratification, sexual excitation gradually and inevitably becomes something “torturing and destructive.” In this way the religious conception of sex as evil and debasing has its foundation in real somatic processes. People who feel a disgust for their body quite naturally develop obsessive concepts of “purity” and “perfection” (p. 144).

It would lead too far afield to discuss here the various ways in which, according to Reich, the “mystical idea of God” becomes anchored in people. These mechanisms may vary in detail, but they all involve the implanting of sexual anxieties; and Reich concludes that from the point of view of energy, mystical feelings are “sexual excitations which have changed their content and goal.” The energy of these emotions is the energy of natural sexuality that has become transformed and attached to mystical, psychic contents. Religious patients, upon establishing a fully satisfying sex life, invariably lose their God-fixation.

Once one comprehends the nature of “religious excitations,” it becomes clear why the free-thought movement “cannot make itself felt as a counter-force” (p. 147). Aside from the fact that in many countries the churches enjoy the support of the state and that generally the mass information media are grossly biased in favor of religion and religious morality, the impact of free-thought propaganda is limited because it relies almost exclusively on intellectual arguments. These are not, indeed, a negligible factor, but they are no match for the “most powerful emotion” on which the mass-psychological influence of religious institutions is based: sexual anxiety and sexual

repression. People with a religious upbringing who, as a result of the study of science and philosophy, have turned into unbelievers very frequently retain religious longings and emotions. Some of them even continue to pray compulsively. This does not prove, as some advocates of religion argue, that religious needs are “eternal and ineradicable.” It does, however, show that “while the religious feeling is opposed by the power of the intellect, its sources have not been touched” (p. 152).

The fight against religion is nevertheless far from hopeless. Mysticism can be eradicated if, in addition to depriving the churches of their “evil right of preparing the children’s minds for the reception of reactionary ideologies” (p. 148), one is guided in the struggle by one’s knowledge that mysticism stems from inhibited sexuality. From this insight it follows incontrovertibly that “full sexual consciousness and a natural regulation of sexual life mean the end of mystical feelings of any kind, that, in other words, natural sexuality is the deadly enemy of mystical religion” (p. 152). Any social efforts that are directed toward making people affirm their sexual rights will ipso facto weaken the forces of mysticism. The most good can be done with children and adolescents. Reich gives numerous instances from his experience in Germany of the “burning interest” of children in sexual questions that made even the most enlightened adults ashamed of their prudishness and hesitation. “Once children and adolescents are reached on a mass basis through their sexual interests,” there will be a “powerful counterweight against the reactionary forces” (p. 169). As for those people who are too old to have their structure basically altered, it is still all to the good to bring “silent suffering to the surface.” They might then be less likely to become instruments in the process of maiming their own children, and they will not continue to support sex-repressive laws.

THE GREAT CULTURAL REVOLUTION. Reich never abandoned the conviction he had reached during his Marxist phase that individual therapy is socially insignificant and that “alteration of the social structure is a prerequisite for an alteration of the psychic structure on a mass scale” (“Character and Society,” p. 255). However, after his separation from organized Marxism, he gradually came to the conclusion that political action was of little consequence and that it was a grave error to judge social developments primarily in terms of a rigid, clear-cut class war. If one is not blinded by the political slogans of an earlier age, one cannot help noticing that we are in the midst of a “deep-reaching revolution of cultural living” (*The Sexual Revolution*, p. xiv).

It is a revolution “without parades, uniforms, drum or cannon salutes,” but, unlike the Russian Revolution of 1917, which was merely “politico-ideological,” it is a “genuine social revolution” (*The Mass Psychology of Fascism*, p. 201). It is not a revolution by the proletariat against the bourgeoisie, and it remains to be seen what major economic changes will accompany it. What is happening is that “the senses of the animal, man, for his natural life functions are awakening from a sleep of thousands of years” (p. xiv). Ever since the beginning of the century, numerous social factors have been operating in the direction of freedom and health. These factors include the creation of huge industrial plants with vast armies of workers of both sexes and the gradual undermining of the authoritarian parental home. There has been a “thorough disintegration of the moralistic ascetic forms of living,” and this “objective loosening of the reactionary fetters on sexuality cannot be undone” (p. 164), regardless of how vociferously the churches and their conscious or unconscious allies continue to preach the old morality.

This “great cultural revolution” is bound to be chaotic and to give rise to all kinds of grotesque developments. The disintegration of the old moralistic institutions and customs expresses itself at first as a rebellion that takes pathological forms, but it is not difficult to see that healthy forces are trying to break through in these pathological manifestations. At one time Reich envisaged a “powerful international organization” that would create an atmosphere of sex-affirmation and thus help to “guide the rebellion into rational channels” (*The Mass Psychology of Fascism*, p. 121). However, regardless of whether any organizations are brought into being which could accelerate the process and make it less painful, there is no reason to “fear for the final outcome.” As yet, human beings, “moved by obscure, ‘oceanic’ feelings, dream instead of mastering their existence; and they perish from these dreams” (*Character Analysis*, p. 324). But when once they master their existence, when they become capable of giving and receiving love and when work will be a source of pleasure and not a burden, this will mean “the death-knell of all transcendental mysticism, of the ‘absolute objective spirit,’” and of all the metaphysical and irrationalist philosophies that are “subsumed under mysticism in the ... wider sense.” An individual “who is sexually happy does not need an inhibiting ‘morality’ or a supernatural ‘religious experience.’ Basically, life is as simple as that. It becomes complicated only by the human structure which is characterized by the fear of life” (*The Sexual Revolution*, p. 269).

REICH’S LAST YEARS

It is not surprising that the ideas sketched in the preceding sections of this entry should have appealed to many who were dissatisfied with the conservative developments of psychoanalysis as well as to those who, disillusioned with the results of communism in Russia, nevertheless strongly believed in social progress. During his early years in the United States, Reich did in fact count among his followers or sympathizers a number of remarkably talented men, from the most varied walks of life, who saw the dawn of a new enlightenment in his psychiatry and in the implications of his theories for education and for the proper direction of social reform. It would be difficult to convey to anybody who was not actually living in New York at that time the enthusiasm that was felt for Reich personally and for what were regarded as his liberating insights. As was to be expected, communists and psychiatrists of other schools were violently hostile, but this only served to heighten people’s admiration for Reich’s independence and for his uncompromising integrity.

It was mentioned previously that Reich himself became less and less interested in psychiatry. He also gradually lost most of his concern to guide into rational channels the “great cultural revolution” that he had diagnosed in his writings. The publications of his last years do indeed contain numerous discussions of social topics, but, at least in the opinion of the present writer, most of what Reich now had to say was flat and trivial. He became increasingly obsessed with the evil conspiracies of “red fascism” (some of Reich’s remarks during this period could be quoted with approval by members of the John Birch Society) and with the menace of the “emotional plague.” This term was originally introduced to refer to the harmful activities of individuals who take out their sexual sickness and frustrations on the rest of humankind, usually under the pretense of promoting some worthy cause.

Reich’s earlier description of emotional plague reactions and motives had been extremely perceptive, but now anybody who was in any way opposed to any of his ideas became automatically classified as an agent of the emotional plague. The writings of the last years are also filled, in a manner reminiscent of Friedrich Nietzsche’s *Ecce Homo*, with hymns of self-praise (sometimes in the third person), and there is much evidence of extreme bitterness toward a world that did not accept or even pay attention to his theories. From the available accounts it appears that Reich had always been impatient and somewhat autocratic, but he had also been singularly compassionate and generous. Dr. Nic Waal, in her sketch of

Reich, describes him as “enormously stimulating and lovable” but adds that in his last years he “became less and less patient, less loving ... and finally pathologically suspicious” (*Wilhelm Reich—A Memorial Volume*, p. 37).

If Reich became increasingly bitter, this was not without a good deal of justification. Right from the beginning, even while he was a psychoanalyst “in good standing,” Reich was the victim of an extraordinary amount of spite and slander. Any study of the records will make it clear that he was treated outrageously by the officials of the Psychoanalytic Association both before and at the Lucerne Conference. We have already mentioned Reich’s troubles in Scandinavia. In New York, he was arrested by the Federal Bureau of Investigation in December 1941 and held at Ellis Island for three weeks. The reasons for the arrest were never divulged. In 1947 an exceptionally vicious campaign was initiated in the *New Republic*, by the journalist Mildred E. Brady. There was not a paragraph in her article that did not contain a major distortion, but it was nevertheless quoted and reprinted all over America.

In an article ten years earlier, the German poet Stephan Lackner had expressed his indignation at the treatment that Reich had received and continued to receive from leading figures among the psychoanalysts and the left-wing parties. “It was not enough,” wrote Lackner, “to expel Reich from their organizations”; in the struggle against this man and his disturbing ideas, “every kind of slander and distortion is a permissible weapon” (*Das neue Tagebuch*, February 1937, p. 140). This last remark applies, word for word, to the campaign instigated by Brady and her associates. In March 1954, the U.S. Food and Drug Administration obtained an injunction against Reich and his foundation, ordering the destruction of all orgone accumulators, all of Reich’s journals, and some of his books; the books that were not destroyed were to be impounded. Among the works proscribed on the ground that they constituted “labeling” of the orgone accumulator were such books as *The Function of the Orgasm* and *Character Analysis*, in which the accumulator is not so much as mentioned.

Nobody except fanatical partisans of Reich can dispute the right of the Food and Drug Administration to intervene. When on the defensive, Reich denied that he had ever claimed any curative powers for the orgone accumulator, but the truth is that the literature is full of such claims. However, granting that the Food and Drug Administration had evidence to show the accumulator medically worthless (no such evidence has ever been published), the injunction is nevertheless a startling docu-

ment constituting a blanket attack on Reich’s character and his entire work.

Reich had two weeks in which to appeal, but to everybody’s consternation he refused to appear in court. Instead, he wrote a letter to the judge in the case, declaring that a court of law was not the appropriate place for adjudicating scientific questions. For some months Reich obeyed the injunction, but in October 1954 he notified the authorities that he was about to resume all the activities of his institute, including the sale of books and periodicals. This led to a trial in 1956, at which Reich was given the maximum sentence of two years in a federal penitentiary. Reich died of a heart attack eight months after he had started serving his sentence. All journals published by Reich’s institute that were seized by government agents were burned in two separate actions in 1956 and 1960, and his books were impounded until they began to be republished by a commercial house in 1960.

There is no doubt in the mind of the present writer that during his last years Reich was mentally ill. Some of those who were close to him deny this, and the prison psychiatrist who examined Reich certified him as sane. Nevertheless, if one reads the records of the trial or the brief that Reich filed in his appeal, one can hardly resist drawing the conclusion that a great man had broken down. Reich finally “went to pieces,” observed Dr. Waal, “partly on his own—but mostly due to other people,” adding that “a human being cannot bear cruelty and loneliness in the long run” (*Wilhelm Reich—A Memorial Volume*, pp. 38–39). It is worth recalling the words of Josef Popper-Lynkeus, whose ideas bear little resemblance to Reich’s but who was also described as “mad” during the better part of his life. “I assure you,” he told his biographer, “[that] of all experiences none is more painful than that of finding oneself described as mad as a consequence of having discovered something that is good and true: of all martyrdoms, this is perhaps the most terrible” (A. Gelber, *Josef Popper-Lynkeus*, p. 101).

Bibliography

The following abbreviations are used throughout; ZPS for *Zeitschrift für politische Psychologie und Sexualökonomie* and IJSO for *International Journal for Sex-Economy and Orgone Research*.

Several biographies of Reich have been announced, but none had been published by the time this entry went to press. The only published sketches of Reich are A. S. Neill’s “The Man Reich” and Nic Waal’s “On Wilhelm Reich,” both in *Wilhelm Reich—A Memorial Volume*, edited by Paul Ritter (London, 1958). There is a good deal of autobiographical material,

especially on his relations with Freud, in Reich's *The Function of the Orgasm*, translated from the German manuscript by T. P. Wolfe (New York: Orgone Institute Press, 1942; paperback reprint, 1961). This book is a good introduction to all of Reich's theories discussed in the present entry. The reader should be warned, however, that in the 1961 reprint the very valuable introduction by Dr. Wolfe has been deleted. *People in Trouble* (Rangeley, ME: Orgone Institute Press, 1953) contains an account of Reich's work at his sex hygiene clinics and of his difficulties with communist functionaries in Germany and Denmark. Reich's attempt to organize an international movement in support of a sex-affirmative culture is described by him in two articles: "Zur Geschichte der Sexpol Bewegung," in *ZPS* 1 (1934): 259–269, and "Geschichte der deutschen Sexpol-Bewegung," in *ZPS* 2 (1935): 64–70. The only published account of Reich's troubles in Norway is Gunnar Leistikow, "The Fascist Newspaper Campaign in Norway," in *IJSO* 1 (1942): 266–273. This article also discusses Reich's troubles in Denmark. Its title is misleading in that many of Reich's opponents were not fascists. Reich's *Listen Little Man!*, translated from the German manuscript by T. P. Wolfe, with illustrations by William Steig (New York: Orgone Institute Press, 1948), is a moving outburst against the various people who harassed and defamed him.

The fullest published account of Reich's technique of vegetotherapy is *Orgasmusreflex, Muskelhaltung und Körperausdruck* (Copenhagen: Sexpol, 1937), parts of which are translated in Chapter 8 of *The Function of the Orgasm* and Chapter 15 of the third edition of *Character Analysis* (New York: Orgone Institute Press, 1949). Various aspects of Reich's new technique are also discussed in the following articles: Odd Havrevold, "Vegetotherapy," in *IJSO* 1 (1942): 65–87, written under the pseudonym Walter Frank; Ola Raknes, "The Treatment of a Depression," in *IJSO* 1 (1942): 163–170, and "Sex-Economy," in *IJSO* 3 (1944): 17–37, written under the pseudonym Carl Arnold. (These pseudonyms were necessary during the Nazi occupation of Norway.)

Child therapy is discussed in Felicia Saxe, "A Case History," in *IJSO* 4 (1945): 59–71, and "Armored Human Beings versus the Healthy Child," in *Annals of the Orgone Institute* 1 (1947): 35–72; and in Nic Waal, "A Case of Anxiety Neurosis in a Small Child," in *Bulletin of the Menninger Clinic* 12 (1948), and "A Special Technique of Psychotherapy with an Autistic Child," in *Emotional Problems of Early Childhood*, edited by G. Caplan (New York: Basic, 1955).

The fullest statement of Reich's views on religion is found in Chapters 6 and 7 of *Massenpsychologie des Faschismus* (Copenhagen: Verlag für Sexualpolitik, 1933), third edition translated by T. P. Wolfe as *The Mass Psychology of Fascism* (New York: Orgone Institute Press, 1946). Discussions of religion strongly influenced by Reich are J. H. Leunbach, "Religion und Sexualität," in *ZPS* 1 (1934): 70–72; Karl Teschitz, "Grundlagen der Religion," in *ZPS* 2 (1935): 103–129, and "Religiöse Ekstase als Ersatz der sexuellen Auslösung," in *ZPS* 4 (1937): 23–34; and Theodor Hartwig, "Religion und Sexualität," in *Der Freidenker* (Bern, April 1936), and "Der Sinn der religiös-sittlichen Erziehung," in *ZPS* 4 (1937): 203–205. Of philosophical interest are Reich's articles "Zur Anwendung der Psychoanalyse in der Geschichtsforschung," in *ZPS* 1 (1934): 4–16, and "Die Funktion der objektiven Wertwelt," in *ZPS* 2 (1935): 32–43.

For some years Reich considered himself a dialectical materialist. His attempt to give empirical meaning to the so-called dialectical laws can be found in *Dialektischer Materialismus und Psychoanalyse* (Berlin, 1929; 2nd ed., Copenhagen, 1934).

Reich's views concerning the relation between society and character structure are stated succinctly in "Charakter und Gesellschaft," in *ZPS* 3 (1936), translated by T. P. Wolfe as "Character and Society," in *IJSO* 1 (1942): 247–256, and much more fully in *The Mass Psychology of Fascism* and in *Die Sexualität im Kulturkampf* (Copenhagen, 1936), translated by T. P. Wolfe as *The Sexual Revolution* (New York: Orgone Institute Press, 1945). Reich's claims about the "function" of sexual suppression are partly based on his anthropological theories, which are an extension of the work of Malinowski. The fullest statement of these theories is found in *Der Einbruch der Sexualmoral* (Berlin: Verlag für Sexualpolitik, 1932). There is a critical discussion of Reich's anthropology in a review of this book by Erich Fromm, in *Zeitschrift für Sozialforschung* 2 (1933): 119–122.

Critical discussions of Reich's character-analytic technique are found in Carl M. Herold, "A Controversy about Technique," in *Psychoanalytic Quarterly* 8 (1939): 219–243; and in Richard Sterba, "Clinical and Therapeutic Aspects of Character Resistance," in *Psychoanalytic Quarterly* 22 (1953): 1–20. The dispute over the existence of "primary masochism" is surveyed in C. C. Flugel, *Man, Morals and Society* (London: Duckworth, 1945). Flugel, after some hesitation, sides with Theodor Reik and Franz Alexander against Reich. Even sympathetic commentators have frequently expressed doubts about what they take to be the excessively simple and "Rousseauist" view concerning the "natural" man that is implicit in many of Reich's discussions. Reich's view on this subject is condemned as "a stale left-over of the eighteenth-century imagination" in Philip Rieff, "The World of Wilhelm Reich," in *Commentary* 38 (September 1964): 50–58. There are replies to Rieff in *Commentary* 39 (February 1965): 19–22. Perhaps the best-known attack on Reich is found in Chapter 21 of Martin Gardner, *Fads and Fallacies in the Name of Science* (New York, 1952; 2nd ed., New York: Dover, 1957). In the opinion of the present writer, Gardner gives an extremely distorted picture of Reich's significance, concentrating on the wild claims of his last years and doing scant justice to the ideas discussed in the present entry.

Various of Reich's theories are sympathetically discussed in Max Hodann, *A History of Modern Morals* (London: Heinemann, 1937); Stephan Lackner, "Ein moderner Ketzler," in *Das neue Tagebuch* (Paris) 5 (1937): 140–141; Harald K. Schjelderup, *Nervose Og Opdragelse* (Oslo, 1937); Neil McInnes, "An Examination of the Work of Wilhelm Reich," in *Hermes* 48 (1946): 26–29; Paul Goodman, "The Political Meaning of Some Recent Revisions of Freud," in *Politics* 2 (1945): 197–203, and "Dr. Reich's Banned Books," in *Kulchur* (1960), reprinted in Goodman's *Utopian Essays and Practical Proposals* (New York: Vintage, 1964), C. Berg, *Psychotherapy* (New York, 1948); Rudolf Brun, *General Theory of Neuroses*, translated by B. Miall (New York, 1951); and R. A. Wilson, "Wilhelm Reich and the Book Burners," in *Minority of One* 3 (February 1961): 6–7. There are constant references to Reich's therapy and to his social theories in the books written by A. S. Neill from 1939 on, such as *The*

Problem Teacher (London: Jenkins, 1939), *Hearts Not Heads in the School* (London: Jenkins, 1945), and *The Problem Family* (New York: Hermitage Press, 1949).

The *Orgone Energy Bulletin* 5 (1953): 1–137, contains a very extensive bibliography of writings by and about Reich up to 1952. Unfortunately all issues of this periodical, as well as all issues of *IJSO*, are among the publications that were burned by the U.S. government.

Bibliography updated by Michael J. Farmer (2005)

REICHENBACH, HANS (1891–1953)

Hans Reichenbach was a leading philosopher of science and a proponent of logical positivism. He made important contributions to the theory of probability and to the philosophical interpretation of the theory of relativity, quantum mechanics, and thermodynamics.

LIFE

Reichenbach studied civil engineering, physics, mathematics, and philosophy at Berlin, Göttingen, and Munich in the 1910s. Among his teachers were neo-Kantian philosopher Ernst Cassirer, mathematician David Hilbert, and physicists Max Planck, Max Born, and Arnold Sommerfeld. Reichenbach received his degree in philosophy from the Friedrich-Alexander University of Erlangen-Nürnberg in 1915 with a dissertation on the theory of probability titled *Der Begriff der Wahrscheinlichkeit für die mathematische Darstellung der Wirklichkeit* (The Concept of Probability for the mathematical Representation of Reality), published in 1916. Between 1917 and 1920, while he was working as a physicist and engineer, Reichenbach attended Albert Einstein's lectures on the theory of relativity at Berlin. He was fascinated by the theory of relativity and in a few years published four books about this subject: *The Theory of Relativity and A Priori Knowledge* (1920), *Axiomatization of the Theory of Relativity* (1924), *From Copernicus to Einstein* (1927), and *The Philosophy of Space and Time* (1928). In 1920 he began teaching at the Technische Hochschule at Stuttgart as private docent.

With the help of Einstein, Planck, and Max von Laue, in 1926 Reichenbach became assistant professor in the physics department of Berlin University. In 1930 he undertook the editorship of the journal *Erkenntnis* (Knowledge) with Rudolf Carnap. In 1933, soon after Adolf Hitler became chancellor of Germany, Reichenbach was dismissed from Berlin University because his family had Jewish origin. He emigrated to Turkey, where he was appointed chief of the philosophy department of Istanbul University with a five-year contract. During his stay in Turkey he published *The Theory of Probability* (1935). In 1938 he moved to the United States, where he became professor at the University of California at Los Angeles. In the following years Reichenbach published *Experience and Prediction* (1938); *Philosophic Foundations of Quantum Mechanics* (1944); *Elements of Symbolic Logic* (1947); "The Philosophical Significance of the Theory of Relativity" in *Albert Einstein: Philosopher-Scientist* (1949), edited by Paul Arthur Schilpp; and *The Rise of Scientific Philosophy* (1951). Reichenbach died in 1953 while he was working on the nature of scientific laws and on the philosophy of time. The two books that came from this work, *Nomological Statements and Admissible Operations* (1954) and *The Direction of Time* (1956), were published posthumously.

COORDINATIVE DEFINITIONS

An important tool introduced by Reichenbach for the philosophical analysis of scientific theories is that of coordinative definitions. According to Reichenbach, a mathematical theory differs from a physical theory because the latter uses a specific type of definition, named coordinative definition, which coordinates (that is associates) some concepts of the theory with physical objects or processes. An example of a coordinative definition is the definition of the standard unit of length in the metric system, which connects the meter with a rod housed in the International Bureau of Weights and Measures in Sèvres, or with a well-defined multiple of the wavelength of a determined chemical element. Another example is the definition of the straight line as the path of a ray of light in vacuum. A scientific theory acquires a physical interpretation only by means of coordinative definitions. Without such type of definitions a theory lacks of a physical interpretation and it is not verifiable, but it is an abstract formal system, whose only requirement is axioms' consistency.

Geometry well illustrates the role of coordinative definitions. In Reichenbach's opinion, there are two different kinds of theories concerning geometry, namely mathematical geometry and physical geometry. Mathematical geometry is a formal system that does not deal with the truth of axioms, but with the proof of theorems—that is, it only searches for the consequences of axioms. Physical geometry is concerned with the real geometry in the physical world; it searches for the truth or falsity of axioms using the methods of the empirical science. The physical geometry derives from the mathematical geometry when appropriate coordinative definitions are added. For example, if the concept of a straight line is coordinated with the path of a ray of light in a vacuum, the theory of relativity shows that the real geometry is a non-Euclidean geometry. Without coordinative definitions, Euclidean and non-Euclidean geometry are nothing but formal systems; with coordinative definitions, they are empirically testable. Coordinative definitions are conventions, because it is admissible to choose a different definition for a concept of a theory. In the case of geometry, with a different definition for the straight line, Euclidean geometry is true. In a sense, choosing between Euclidean and non-Euclidean geometry is not a matter of facts, but a matter of convention.

RELATIVITY OF GEOMETRY

Reichenbach insists on the importance of the coordinative definitions in his philosophical analysis of the theory

of relativity, especially in connection with the problem of determining the geometry of this world. In principle, scientists can discriminate between different geometry by means of measurements. For example, on the surface of a sphere, the ratio of the circumference of a circle to its diameter is less than π , whereas on the surface of a plane this ratio is equal to π . With a simple measurement of a circumference and of its diameter, we can discover we live on a sphere (the surface of Earth) and not on a plane. In the same way, using more subtle measurements, scientists can discover we live in a non-Euclidean space. However, there is a fundamental question: is measuring a matter of facts or does it depend on definitions? Reichenbach proposes the following problem, discussed in *The Philosophy of Space and Time*: is the length of a rod altered when the rod is moved from one point of space, say A, to another point, say B? We know many circumstances in which the length is altered. For example, the temperature in A can differ from the temperature in B. However, the temperature acts in a different way on different substances. If the temperature is different in A and in B, then two rods of different material, such as wood and steel, which have the same length in A, will have a different length in B. So we can recognize a difference in temperature and use suitable procedures to eliminate variations in measurement due to variations in temperature. In general, this is also possible for every differential force—that is, for every force that acts in a different way on different substances. But there is also another type of forces, called universal forces, which produce the same effect on all types of matter.

The best-known universal force is gravity, whose effect is the same on all bodies. What happens if a universal force alters the length of all rods, in the same way, when they are moved from A to B? By the very definition of universal forces, there are no observable effects. If we do not exclude universal forces, we cannot know whether the length of two measuring rods, which are equal when they are in the same point of space, is the same when the two rods are in two different points of space. Excluding universal forces is nothing but a coordinative definition. We can also adopt a different definition, in which the length of a rod depends on the point of space in which the rod stays. So the result of a measurement depends on the coordinative definition we choose. As a consequence, the geometrical form of a body, which depends on the result of measurements, is a matter of definition. The most important philosophical consequence of this analysis concerns the relativity of geometry. If a set of measurements supports a geometry G, we can arbitrarily choose a different geometry G' and adopt a different set of coordinative definitions so that the same set of meas-

urements supports G' , too. This is the principle of relativity of geometry, which states that all geometrical systems are equivalent. According to Reichenbach, it falsifies the alleged a priori character of Euclidean geometry and thus falsifies the Kantian philosophy of space.

CAUSAL ANOMALIES

The principle of relativity of geometry is true for metric relationships—that is, for geometric properties of bodies depending on the measurement of distances, angles, and areas. The situation seems different when we are concerned about topology, which deals with the order of space—that is, the way in which the points of space are placed in relation to one another. A typical topological relationship is “point A is between points B and C.” The surface of a sphere and the surface of a plane are equivalent with respect to metrics, provided an appropriate choice of the coordinative definitions, but they differ from a topological point of view.

Consider the following example presented by Reichenbach in *The Philosophy of Space and Time*. Intelligent beings living on the surface of a sphere can adopt coordinative definitions that, from a metric point of view, transform the surface of the sphere into the surface of a plane. However, there is an additional difficulty: Because the surface of a sphere is finite, it is possible to do a round-the-world tour, walking along a straight line from a point A and eventually returning to the point A itself. Of course this is impossible on a plane, and thus it would seem that these intelligent beings have to abandon their original idea that they are living on a plane and instead must recognize they are on a sphere. But this is not true, because another explanation is possible: They can assert that they had walked in a straight line to point B, which is different from point A but, in all other respects, is identical to A. They can also fabricate a fictitious theory of pre-established harmony—according to which everything that occurs in A immediately occurs in B—in order to explain the similarity between A and B. This last possibility entails an anomaly in the law of causality. We can reject causal anomalies, but only by means of an arbitrary definition. Thus topology depends on coordinative definitions, and the principle of relativity of geometry also holds for topology. According to Reichenbach, this example is another falsification of Kantian theory of synthetic a priori. In Kantian philosophy, the Euclidean geometry and the law of causality are both a priori, but if Euclidean geometry is an a priori truth, normal causality can be false; if normal causality is an a priori truth, Euclidean geometry can be false. We arbitrarily can choose the

geometry, or we arbitrarily can choose the causality, but we cannot choose both.

QUANTUM MECHANICS

Quantum mechanics differs from the other scientific theories because in this theory there is no possibility to introduce normal causality. No set of coordinative definitions can give an exhaustive interpretation of quantum mechanics free from causal anomalies.

It is important to explain some concepts used by Reichenbach in *Philosophical Foundations of Quantum Mechanics*, his main work about quantum mechanics. Using a wider sense of the word “observable,” some events occurring in quantum mechanics are observable; they are events consisting in coincidences between particles or between particles and macroscopic material, like the collision of an electron on a screen, signaled by a flash of light. Events between such types of coincidences are unobservable; an example is the path of an electron between the source and the screen on which it collides.

Quantum observable events are called, by Reichenbach, phenomena, whereas unobservable ones are called interphenomena. Reichenbach explains that there are three main interpretations concerning interphenomena: wave interpretation, according to which matter consists of waves; corpuscular interpretation, according to which matter consists of particles; and Bohr-Heisenberg interpretation, according to which statements about interphenomena are meaningless. The first two interpretations are called exhaustive interpretations, because they include a complete description of interphenomena. The last is a restricted interpretation, because it prohibits assertions about interphenomena. A normal system is an interpretation in which the laws of nature are the same for phenomena and interphenomena. This definition of a normal system is modeled on a basic property of classical physics: the laws of nature are the same whether or not the object is observed.

With these definitions, it is possible to formulate Reichenbach’s principle of anomaly in quantum mechanics: there is no normal system. Thus causal anomalies cannot be removed from quantum mechanics. However, there is another peculiarity in quantum mechanics: for every experiment there exists an exhaustive interpretation—which is a wave or a corpuscular interpretation—that provides a normal system, although limited to this experiment. In other words, there does not exist an interpretation free from all causal anomalies, but for every causal anomaly there does exist an interpretation that ruled out this anomaly. For example, if we adopt the cor-

puscular interpretation, we have to face causal anomalies raising from some experiments, such as the two-slits experiment. In this experiment a beam of electrons is directed toward a diaphragm with two open slits and an interference pattern is produced on a screen behind the diaphragm; the probability that an electron, passing through an open slit, will reach the screen at a given point is depending on whether the other slit is open or closed—with the electron behaving as if it is informed about the state of the other slit.

This causal anomaly is eliminated if we adopt the wave interpretation, according to which the interference patterns are produced by waves in conformity with Huygens's principle. The wave interpretation is in turn affected by other anomalies raising from the so-called reduction of the wave packet: The wave originating from an open slit occupies a hemisphere centered on the slit, but when the wave hits the screen, a flash is produced in a point only and the wave disappears in all other points. Apparently all physical properties transported by the wave, such as momentum and energy, suddenly materialized in a single point, even if they were distant from this point. This situation is explained without anomalies by the corpuscular interpretation. According to Reichenbach, in every experiment about quantum mechanics we can adopt an interpretation free from causal anomalies, but we have to use a different interpretation in a different experiment. Only two interpretations are required: the wave and the corpuscular interpretation. This is the real meaning of the duality of wave and corpuscle in quantum physics. The possibility of eliminating causal anomalies from every quantum experiment is called, by Reichenbach, the principle of eliminability of causal anomalies.

The Bohr-Heisenberg restricted interpretation of interphenomena named after Danish physicist Niels Bohr and German physicist Werner Karl Heisenberg, states that speaking about values of unmeasured physical quantities is meaningless. Reichenbach criticizes the Bohr-Heisenberg interpretation on two points. First, Heisenberg's indeterminacy principle becomes a meta-statement about the semantics of the language of physics; second, this interpretation implies the presence of meaningless statements in the language of physics.

Using a three-valued logic, in which admissible truth values are *truth*, *falsehood*, and *indeterminacy*, Reichenbach constructs another restrictive interpretation in which a statement about an unmeasured physical quantity can be neither true nor false, but indeterminate.

INTERPRETATIONS OF REICHENBACH'S PHILOSOPHY

An open question regards the relation between Reichenbach and conventionalism. His insistence on the major role played by the coordinative definitions, the relativity of geometry, the equivalence between wave and corpuscular interpretation of quantum mechanics has suggested that his philosophy can be ascribed to conventionalism. In Reichenbach's works there are some points corroborating this view. For example, he asserts that the philosophical meaning of the theory of relativity is that this theory proves the necessity of coordinative definitions, which are arbitrary, in situations in which empirical relations had been previously assumed. But there are also some elements against the conventionalist reading of Reichenbach's philosophy, as seen in the last paragraph of *The Philosophy of Space and Time*, in which Reichenbach affirms that the reality of space and time is an irrefutable consequence of his epistemological analysis; it is an assertion apparently incompatible with conventionalism. As an example of the debate about Reichenbach's attitude toward conventionalism, it is possible to mention the conventionalist interpretation of Reichenbach's philosophy developed by Adolf Grünbaum in *Philosophical Problems of Space and Time* (1973) and Hilary Putnam's counterarguments offered in "The Refutation of Conventionalism" (1975).

A different explication of Reichenbach's philosophy, based on an analysis of the role of the coordinative definitions in the light of Kantian philosophy, is advanced by Michael Friedman and exposed in *Reconsidering Logical Positivism* (1999). According to Friedman's interpretation, Reichenbach, in his first published work on the theory of relativity (*Theory of Relativity and A Priori Knowledge*), distinguishes two different meanings of synthetic a priori, which are united in Kantian philosophy. In the first meaning, a synthetic a priori judgment is necessary and thus not modifiable; in the second meaning, a synthetic a priori statement is constitutive of the object. The coordinative definitions are not necessary judgments, because we can make use of a different definition. Moreover, all coordinative definitions are subjected to changes with the evolution of knowledge, so they are modifiable. Thus they are not a priori in the first meaning present in Kantian philosophy. But the coordinative definitions are required to give an empirical interpretation to a theory and so they are constitutive of the object of knowledge. Thus they are synthetic a priori in the second meaning present in Kantian philosophy. Friedman calls this type of a priori judgment "constitutive, rela-

tivized a priori” (1999, p. 62), because they are a priori in the constitutive sense, relative to a given theory.

Surely Kantian philosophy exerts a great influence on Reichenbach. He professes admiration for Kant in his first works. In the article “Kant und die Naturwissenschaft” (1933, p. 626) he says, “There is no doubt that he [Kant] was one of the few thinkers whose work showed the way on which the contemporary philosophy of natural science continues to proceed.” According to Reichenbach, Kantian philosophy of nature is a meaningful theory, although it is superseded by the outcomes of contemporary physics. Later, Reichenbach accentuates his departure from Kant, stressing his criticism of synthetic a priori and developing many arguments against Kantian philosophy.

REID, THOMAS

(1710–1796)

Thomas Reid was the founder of the Scottish “Common Sense” school of philosophy. A contemporary and critic of David Hume, he is best known for his staunch defense of common sense and trenchant opposition to the “way of ideas,” the theory that the immediate objects of perception and other cognitive acts are always internal images or ideas, not external physical objects. His views exerted a good deal of influence until the mid-nineteenth century or so, when they began to be eclipsed by absolute idealism, pragmatism, and other philosophical movements, but they have been the subject of renewed interest from the 1970s on.

After being educated at Marischal College in Aberdeen, Scotland, Reid served for fifteen years as a parish minister in nearby New Machar. In 1752 he was appointed professor at King’s College in Aberdeen, where he taught mathematics, physics, and philosophy, among other subjects. He tells us that in his youth he believed nearly the entire philosophy of George Berkeley but that a reading of Hume’s *Treatise of Human Nature* (1739–1740) convinced him (by carrying Berkeley’s philosophy to its logical conclusions) that there must be some original defect in it. Reid identified this defect as the theory of ideas, which he went on to challenge in college lectures, meetings of the Aberdeen Philosophical Society, and two books. In 1764 he published his first major work, *An Inquiry into the Human Mind on the Principles of Common Sense*, in which he set forth his reasons for opposing the theory of ideas and offered an alternative theory of how we gain knowledge by means of the various senses.

In the same year he accepted the chair in moral philosophy at Glasgow, succeeding Adam Smith. He lectured there until 1780, when he resigned to prepare his last two major works: *Essays on the Intellectual Powers of Man* (1785), devoted to the contributions of perception, memory, reason, and other cognitive powers to human knowledge, and *Essays on the Active Powers of the Human Mind* (1788), devoted to the nature of action, will, freedom, and morality.

This article provides a synopsis of Reid's main views more or less in the order in which he presented them in his three published books: the *Inquiry* (abbreviated as Inq.), the *Intellectual Powers* (abbreviated as IP), and the *Active Powers* (abbreviated as AP). Numbers separated by a period refer to chapter and section numbers in the *Inquiry* and to essay and chapter numbers in the two volumes of *Essays*.

CRITIQUE OF THE THEORY OF IDEAS

Almost alone among the great modern philosophers, Reid espoused a direct realist theory of perception. He repudiated the assumption that what is immediately present to the mind is never an external thing, but only an internal image, impression, representation, or (to use the most common eighteenth-century term) *idea*. Ideas were usually conceived of as mental entities that existed only as long as the mind was aware of them. Reid found the theory of ideas to be taken for granted in the work of most of his philosophical predecessors, including René Descartes, Nicolas Malebranche, Antoine Arnauld, John Locke, Berkeley, and Hume. Some of these philosophers (for example, Descartes and Locke) were realists, believing that ideas are caused in us by physical objects existing outside the mind. Others (notably, Berkeley) were idealists, repudiating the existence of a world outside the mind and believing that the things we call physical objects are simply bundles of ideas. In either case, we are cut off from direct perception of the physical world, either because there is no physical world to be perceived, or because our perception of it is indirect—not strictly perception at all, but inference based on what we do perceive, namely, ideas.

Reid makes at least three important points against the theory of ideas. First, the arguments in favor of the theory are weak and without cogency; second, the theory does nothing to explain how perception is possible; third, the theory stands in the way of our knowing or even being able to conceive of the physical world.

One of the arguments for the theory of ideas that Reid singles out for criticism is a version of the argument

from perceptual relativity. Hume had claimed that the “universal and primary opinion of all men” that they perceive external objects directly is “destroyed by the slightest philosophy,” offering the following argument in section 12 of the *Enquiry concerning Human Understanding*: “The table, which we see, seems to diminish as we remove further from it; but the real table, which exists independent of us, suffers no alteration. It was therefore nothing but its image which was present to the mind.” Hume's argument may be cast into the following syllogism: (1) What I see diminishes in magnitude as I retreat from it; (2) the table itself does not diminish in magnitude as I retreat from it; (3) therefore, what I see is not the table itself (but only an image or idea).

Reid contends that Hume's premises are true only if we restate them as follows (IP 2.14, p. 182): (1) What I see diminishes in *apparent* magnitude as I retreat from it; (2) the table itself does not diminish in *real* magnitude as I retreat from it; (3) therefore, what I see is not the table (but only an image or idea).

The real magnitude of an object (for example, the edge of a table) is an intrinsic property of it, measured in feet or inches, whereas the apparent magnitude of an object is a relation between the object and a perceiver (or his vantage point), measured by the angle the object subtends at the eye. Reid takes the terminology of “real” versus “apparent” from the astronomy of his day; it is not necessarily implied that there is anything illusory about apparent magnitude. It is easy to see that apparent magnitude varies with the distance between object and perceiver (objects subtending smaller angles when further away) whereas real magnitude does not. Once we record these facts correctly, as in Reid's version of the syllogism, we see that the conclusion of the argument does not follow from the premises. Moreover, Reid would resist the thought that if O has greater apparent magnitude when seen from p than when seen from p', that is because it presents a larger image to the observer at p than to the observer at p'. Apparent magnitude is a strictly dyadic relation, involving only the object and the perceiver (or his vantage point) and no third thing such as a mental image.

Reid's second point against the hypothesis of ideas is “that ideas do not make any of the operations of the mind to be better understood” (p. 184). Ideas had been thought necessary to explain how we perceive things that are distant, remember things that are past, or imagine things that do not exist at all, but Reid argues that all such explanations are worthless. They presuppose that ideas themselves can somehow be of the remote, the past, or the

nonexistent. But if ideas can do that, what prevents the simple idealess acts of perceiving, remembering, and imagining from doing it as well? Moreover, our ability to be aware of ideas themselves is no less mysterious than our ability to be aware of things that are not ideas.

It is as difficult to conceive how the mind perceives images in the brain as how it perceives things more distant. If any man will shew how the mind may perceive images in the brain, I will undertake to shew how it may perceive the most distant objects: for if we give eyes to the mind, to perceive what is transacted at home in its dark chamber, why may we not make these eyes a little longer-sighted? (Inq. 6.12, p. 121)

Reid's third point against the theory of ideas is "that the natural and necessary consequences of it furnish a just prejudice against it to every man who pays a due regard to the common sense of mankind" (p. 185). Chief among these consequences is that if we do not simply see or touch external objects, it becomes necessary to prove their existence by arguments. Descartes, Malebranche, and Locke all tried to muster such arguments, but none of the arguments is convincing. Reid thus thinks that skepticism about the material world is a built-in consequence of the theory of ideas. By contrast, if what we see and touch are not ideas but things in the external world, as in Reid's own view, this source of skepticism is eliminated.

SENSATION AND PERCEPTION

A sensation is an event that occurs in a sentient subject when he or she smells a rose or tastes a fig. It lacks figure and extension and other qualities of bodies, being entirely mental. Reid calls sensations "principles of belief," by which he means that when we have a sensation and attend to it, we cannot help believing that it exists, that a subject of it exists (ourselves), and that some external object (for example, some quality in the rose) exists as its cause.

Reid is among the first to distinguish between sensation and perception. He explains this distinction as follows:

Thus, *I feel a pain*; *I see a tree*: the first denoteth a sensation, the last a perception. The grammatical analysis of both expressions is the same: for both consist of an active verb and an object. But, if we attend to the things signified by these expressions, we shall find, that in the first, the distinction between the act and the object is not real but grammatical; in the second, the distinction is not only grammatical but real. The form

of the expression, *I feel pain*, might seem to imply, that the feeling is something distinct from the pain felt; yet, in reality, there is no distinction. As *thinking a thought* is an expression which could signify no more than *thinking*, so *feeling a pain* signifies no more than *being pained*. What we have said of pain is applicable to every other mere sensation. (Inq. 6.20, pp. 167–68)

When I perceive a tree, there is an object (the tree) apart from my act of seeing, but when I have a sensation, there is no object apart from the act of sensing. As he defines sensation in the *Intellectual Powers*, it is an act of the mind "which may be distinguished from all others by this, that it hath no object distinct from itself" (IP 1.1, p. 36). That formulation is ambiguous: Does an act of sensing have itself for its object, or does it have no object at all? Although Reid's language often suggests the former option, his proposal that *being pained* is the model for all sensation suggests the latter option. If we take Reid in the latter way, he is a precursor of "adverbial" theories of sensation, such as were developed by C. J. Ducasse and Roderick Chisholm two centuries later: to have a sensation of red is not to sense something, but is simply to sense somehow—"redly," as the adverbial theory styles it.

Some critics of Reid have thought that his sensations are simply ideas under a new name, but there are important differences—especially if he holds an adverbial theory rather than a theory that divides sensation into act and object. If sensing required its own special objects, the argument from perceptual relativity against direct realism could be reinstated. The mountain that looks blue from a distance and green from close up would do so by generating first blue and then green sensory objects in my mind, and these variously colored objects would have to be distinct from the unchanging mountain. They would displace the mountain itself as my object of direct awareness. But Reidian sensations do not have objects to get in the way of direct perception of external things.

Although sensations do not *have* objects, they can *become* objects for us, in the sense that we can know through proper attention what sorts of sensations we are having. Indeed, Reid thinks that if we attend carefully to our sensations, we can know perfectly what they are like and can scarcely make any mistake about them. Yet typically we pay so little attention to them that we become almost oblivious to them; they serve as mere cues or signs from which our minds leap instantly to other things that they signify.

Our apprehension of that which sensations signify is *perception*. Reid's official characterization of perception involves three elements: conception, belief, and immediacy:

If, therefore, we attend to that act of our mind which we call the perception of an external object of sense, we shall find in it these three things:—*First*, Some conception or notion of the object perceived; *Secondly*, A strong and irresistible conviction of its present existence; and *Thirdly*, That this conviction and belief are immediate, and not the effect of reasoning. (IP 2.5, p. 96; cf. Inq. 6.20, p. 168)

Note that this definition makes no mention of sensation. Although Reid says that sensation generally serves as the trigger for the conception and belief involved in perception, perception proper is just conception plus immediate belief. Reid thinks it possible that perception should occur in the absence of sensation, and he holds that there is one variety of human perception that actually does occur without any characteristic sensation: namely, the perception of visible figure. Reid thus deemphasizes the role of sensation in perception in a way that some contemporary theorists (for example, James J. Gibson) would applaud. By the same token, however, his threefold definition may strike others as leaving out precisely that by which a genuine perception of a snake in the path ahead is distinguished from the conception and immediate belief in it one may form as the result of a friend's warning. Here Reid's views may gain in plausibility if we reckon his "conception" as something like what Bertrand Russell called knowledge by acquaintance. It is not necessarily the exercise of a concept in mere thought.

REID'S NATIVISM

Reid thought that much of what he found alarming in Hume's philosophy stemmed from Hume's adherence to the empiricist maxim that we have no ideas or notions that are not derived from previous impressions or sensations. It is by this principle that Hume was led to conclude that we have no legitimate notions of objects existing unperceived, of causal connections amounting to more than constant conjunctions, and of a self that is the subject of various mental operations. Reid sought to overthrow Hume's philosophy by undermining its foundations, and for this purpose he tackled the empiricist principle head-on. He pointed to a notion that he thought Hume would surely concede that we possess—the notion of *extension*, or being spread out in space—and contended that this notion lacks a proper Humean

birthright in our sensations. If it were once acknowledged that not even so uncontroversial a notion as extension can be extracted from our sensations or impressions, Reid thought, the way would be open for recognizing the legitimacy of other notions with no sensory origin, such as the ideas of agency, self, and an external world.

To back up his contention that the notion of extension is not derived from sensation, Reid offers a thought experiment he calls his *experimentum crucis* (Inq. 5.6 and 5.7, pp. 65–72). He asks us to imagine a being furnished with a progressively richer array of sensations, beginning with those caused by the prick of a pin, advancing to more complex sensations such as those caused by the pressure of a blunt object against his or her body, and culminating with the sensations accompanying the motion of his or her limbs. He asks at each step in the series whether those sensory materials would suffice to give a being who reflected upon them a conception of extension, and his answer is no. Positively, Reid's doctrine is that the conception of extension is innate—not in the sense that we have it from birth, but in the sense that it is triggered in us by certain sensations from which it could never have been derived from any process of abstraction or ratiocination. We are enabled to form the conception of extended things only because we are innately programmed to do so.

For further light on the import of Reid's nativism, we may restate it in terms of the threefold classification of natural signs he offers in sections 4.2 and 5.3 of the *Inquiry*. Reid first divides signs into the artificial and the natural. In the former class, the connection between sign and thing signified is established by compact or convention, as with the words of human language. In the latter class, the connection between sign and thing signified is established by nature, as with smoke and fire and other cases of effect and cause. Reid then further divides natural signs into three classes. In the first class, the connection between sign and thing signified is "established by nature, but discovered only by experience" (Inq. 5.3, p. 59), as in the example of smoke and fire already given. In the second class, the connection is "not only established by nature, but discovered to us by a natural principle, without reasoning or experience" (Inq. 5.3, p. 60).

Reid thinks that certain features of the human countenance are signs in this sense of thoughts and other mental states. For example, an infant is innately disposed to read a smile on its mother's face as a sign of approval without having to learn this connection through experience. Unless there were a basic repertoire of natural signs of this second class, Reid believes, the signification of arti-

ficial signs could never be agreed upon or learned. Finally, in the third class are those signs “which, though we never before had any notion or conception of the thing signified, do suggest it, or conjure it up, as it were, by a natural kind of magic” (Inq. 5.3, p. 60). Not only is the *connection* between sign and thing signified innately programmed into our constitution (as with signs of the second class), but also the very *notion* of the thing signified is innate in the sense that it is in no way derivable by abstraction from any of our sensations. Reid believes that the tactile sensations to which we respond with conceptions of extended bodies are natural signs belonging to this third class.

Reid takes his nativism to afford an answer to an argument for skepticism he finds embodied in the combined philosophies of Berkeley and Hume. He formulates the argument as follows (Inq 5.8, p. 75): (1) We can have no conception of anything but what either resembles or is deducible from our sensations; (2) nothing resembles or is deducible from sensations but other sensations; (3) therefore, we can have no conception of anything but sensations.

If the argument were correct in both its premises, it would follow that we cannot even *conceive* of, let alone have knowledge of, a world lying beyond our sensations. Reid thinks the second premise is correct, and he credits Berkeley with having made it evident. But he thinks the first premise—which states in Reid’s language Hume’s principle that all our ideas are copied from precedent impressions—is false. “That we have clear and distinct conceptions of extension, figure, motion, and other attributes of body, which are neither sensations, nor like any sensation, is a fact of which we may be as certain, as that we have sensations” (Inq. 5.8, p. 76).

THE MECHANICS AND GEOMETRY OF VISION

More than half of the *Inquiry* is devoted to vision, which Reid regards as the noblest of the senses. It informs us of the properties of objects far distant, such as the sun and the moon, and it can disclose in a glance the figure of a cathedral, whose delineation by touch would be the work of a lifetime.

Reid provided solutions to a number of puzzles about vision that lie today within the province of cognitive science rather than philosophy. For example, why do we see things upright despite having inverted retinal images of them? To explain this, Reid appeals to the law that an object will be seen in the direction of a straight line drawn from the point of retinal stimulation through

the center of the eye and into ambient space. Why do we normally see objects single despite having two retinal images of them, yet under certain circumstances see them double? Reid’s answer appeals to the law of corresponding retinal points: If rays from an object fall on points of the two retinas lying at equal distances and directions from their centers, the object will be seen as single, but otherwise as double.

One of Reid’s more remarkable findings is that the visible figures of objects are governed by a non-Euclidean geometry. Reid believed that sight by itself (before we have learned any correlations with touch) informs us only of the two-dimensional spatial features of objects. Although the objects we see are at a distance from us (*pace* Berkeley), the eye is incapable of making any discriminations of depth. To an eye placed at the center of a sphere and looking out, great circles on the surface of the sphere (whose outward curvature is invisible to the eye) must appear as straight lines, and every figure seen by the eye must have the same geometrical properties as some figure drawn upon the sphere. In consequence of this, Reid argued that the geometry of visibles is what we would nowadays classify as a Riemannian geometry. A visible triangle, unlike a triangle perceived by touch, always has an angle sum at least slightly greater than 180 degrees, and no two visibly straight lines are ever strictly parallel.

MEMORY

Essay III of the *Intellectual Powers* is devoted to memory. Reid characterizes memory as “an immediate knowledge of things past” (IP 3.1, p. 253). There are two senses in which this is true. First, the object of memory is the very thing or event formerly perceived, not some present idea or simulacrum of it (Inq. 2.3, p. 28). Second, the knowledge one has by memory of this past object is noninferential; it does not rest on any reasoning from premises. Memory is thus like perception for Reid in involving both the conception of an object and an immediate belief in its existence; but it differs from perception because the object is, and is believed to be, past. Reid is severely critical of Hume’s attempt to distinguish imagining, remembering, and perceiving solely in terms of the force and vivacity of their objects.

Reid criticizes Locke’s view that memory is what constitutes personal identity—that person A is identical with person B who existed in the past if and only if A remembers what B did. He insists that memory is the *evidence* of personal identity, rather than that in which it consists (IP 3.4, p. 265). He also presents the famous

“brave officer” objection to Locke’s theory, courtesy of his friend George Campbell: Suppose a man who has become a general late in life remembers capturing the enemy flag as a young officer; that as an officer he remembered being flogged as a boy for robbing an orchard; and that as a general he no longer remembers being flogged as a boy. It follows from Locke’s theory that the general both is and is not the same person as the boy (IP 3.6, p. 276).

CONCEPTION AND ABSTRACTION

Essays IV and V of the *Intellectual Powers* are devoted to conception and abstraction. Conception, the most basic operation of the mind, is “that operation of the understanding which the logicians call *simple apprehension*,” that is, the apprehension of a thing without any belief or judgment about it (IP 4.1, p. 295). “Judgment can be expressed by a proposition only, and a proposition is a complete sentence; but simple apprehension may be expressed by a word or words, which make no complete sentence” (IP 6.1, p. 408). The objects of conception expressed by words or subsentential phrases are either individuals or universals. What Reid calls conception should not be confused with conceptualization—that is, subsuming something under a concept—for the latter is judgment, and conception is more basic than judgment.

Reid holds that all the operations of our minds except sensation have objects distinct from themselves. “He that conceives, must conceive something” (IP 4.1, p. 311), and the same goes for perception and memory. It is a distinctive feature of conception, however, that its objects need not exist: “it is not employed solely about things which have existence” (IP 4.1, p. 310).

On this point, Reid is sometimes seen as a precursor of Alexius Meinong, who held that there can be cognitive relations to the utterly nonexistent and that a thing therefore need not exist in order to stand in relations. Meinong’s view strikes many as paradoxical. Yet Reid makes it look like one more piece of common sense or, at any rate, a consequence of two pieces of common sense (IP 4.1, p. 311): (1) I can conceive of a centaur; (2) no centaur exists; (3) therefore, I can conceive of what does not exist. In case anyone objects that the truth in premise 1 is simply that I can conceive of the *idea* of a centaur, which *does* exist, Reid is ready with a reply: I know the difference between conceiving of a centaur and conceiving of the idea of a centaur, and I can assure you that I am doing the former rather than the latter (IP 4.2, p. 321).

Reid’s view that the objects of conception may be nonexistent has an interesting application to the problem of abstract ideas, which pitted Locke against Berkeley and

Hume. On this topic, Reid writes, “Mr. Locke and his two antagonists have divided the truth between them” (IP 5.6, p. 394). Locke saw clearly “that the power of forming abstract and general conceptions is one of the most distinguishing powers of the human mind,” but he did not see “that this power is perfectly irreconcilable to his doctrine concerning ideas.” Berkeley and Hume “saw this inconsistency; but instead of rejecting the hypothesis of ideas, they explain away the power of abstraction.”

To see how Locke and his critics “divided the truth between them,” consider the following inconsistent triad of propositions:

- (1) We are sometimes aware in thought of the general and the abstract—in Reid’s terminology, we have the power of forming abstract and general conceptions.
- (2) We can only be aware of what exists: “in all of the operations of the understanding, there must be an object of thought, which really exists while we think of it” (IP 4.2, p. 312).
- (3) General entities have no existence: “every thing that really exists is an individual” (IP 5.6, p. 393).

As Reid saw it, Locke accepted both 1 and 2 and was therefore driven to deny 3, despite his affirmation of it elsewhere. He posited “abstract general ideas,” such as the infamous image of a triangle that is neither isosceles nor scalene, as merely generic entities existing in the mind. Berkeley and Hume, on the other hand, both accepted 2 and 3, and were thus led to reject 1. Not believing that entities such as Locke’s merely generic triangle could exist even in the mind, they denied that we are ever aware of general entities. Thus were born their attempts to explain how we can think generally (for example, in proving propositions about all triangles) by means of ideas that are particular.

Reid’s novelty is to deny proposition 2, which he castigates as one of the prejudices giving rise to the theory of ideas. It led all three of his predecessors in the British Empiricist tradition to affirm that the immediate object of awareness, in conception as well as in perception, must be an idea. By denying 2, Reid was enabled to uphold both 1 and 3, thus collecting together the truths his predecessors had divided between them.

FIRST PRINCIPLES

Essay VI of the *Intellectual Powers* contains an extensive and important treatment of what Reid calls first principles. A first principle is a self-evident proposition—a proposition that is evident to us without need of any rea-

sons to support it. Like Aristotle, Reid thinks that our knowledge must ultimately rest on first principles, for without them we would be faced with an infinite regress of supporting propositions. He may therefore be classified as an epistemological foundationalist. Reid believes there are first principles both of necessary and of contingent truths. The first principles of necessary truths include axioms of logic, mathematics, grammar, metaphysics, and morals. The first principles of contingent truths include principles pertaining to the deliverances of consciousness (Reid's term for introspection), perception, memory, inductive reasoning, and others of our faculties.

In Reid's enumeration of the first principles of contingent truths, there is a subtle ambiguity that greatly affects how his epistemology is to be interpreted. Here is how he formulates Principle 1, which gives us the first principle(s) regarding consciousness: "First, then, I hold, as a first principle, the existence of every thing of which I am conscious" (EIP 6.5, p. 470). Putting this in terms of truth rather than existence, he might just as well have said that he holds, as a first principle, the truth of every proposition to which consciousness testifies. The ambiguity in Principle 1 may then be brought out by the following two ways of symbolizing it, where "Cp" is short for "I am conscious that p":

1.1 It is a first principle that $(p)(Cp \rightarrow p)$. (It is a first principle that for any proposition p, if I am conscious that p, then p.)

1.2 $(p)(Cp \rightarrow \text{it is a first principle that } p)$. (For any proposition p, if I am conscious that p, then it is a first principle that p.)

The difference between the formulations is this: 1.1 says that it is a first principle that all the deliverances of consciousness are true. In other words, 1.1 gives us *one general proposition* as first principle. 1.2, on the other hand, says that each of the deliverances of consciousness—which may include propositions such as *I am now in pain*—are themselves first principles. So 1.2 gives us *many particular propositions* as first principles. A similar ambiguity holds in regard to the first principles of perception and memory.

How should Reid's first principles be understood—as general or particular? Perhaps the best overall interpretation of Reid's epistemology is provided by the particularist construction. At the very least, his epistemology must be understood as recognizing particular first principles even it recognizes general first principles as well.

If Reid's first principles are construed in the particularist way, he is not only a foundationalist in his epistemology but also (in one important sense) an *externalist*. Externalists hold that there are sources or factors that give a subject knowledge even if the subject does not know anything about how the factors work or whether they are reliable. On the particularist construction of Reid's principles, the mere fact that a proposition is a deliverance of perception, memory, or consciousness suffices to make that proposition evident (and thus, in favorable circumstances, known). To know that there is a tree over there, for example, one need only have a perception of a tree. It is not necessary for the subject to know anything about the reliability of sense perception, which may be a matter to which he has never given any thought. On the generalist construction of the principles, by contrast, the subject would presumably have to know that the general principles are true in order for knowledge of particular propositions to arise in accordance with them. In other words, he would have to know his faculties are reliable before they could be sources of any other knowledge. That puts an obstacle in the way of knowledge that skeptics might claim to be insurmountable.

It may be useful to summarize by drawing together the various things Reid has to say in response to skepticism about the material world. First, what skeptical philosophers profess cannot be believed and is not believed even by skeptics themselves. This is a point that Hume famously admitted, and it may be questioned what force it has against the truth or reasonableness of the skeptic's position. Second, the argument that we cannot even conceive of a material world is answered by Reid's nativism, according to which we are endowed by our constitution with conceptions of extended external objects.

Third, the argument that knowledge of the external world must be based on problematic inferences from our ideas is undercut by Reid's attack on the theory of the ideas. Fourth, the position of the "semiskeptical," who says we can be certain about the deliverances of our consciousness but not about anything else, is objectionably arbitrary. For who can prove that consciousness never errs? And what reason is there to believe the deliverances of consciousness that is not a reason for believing the deliverances of our other faculties as well? (Inq. 5.7, p. 71).

Finally, the position of the total skeptic, who refuses to accept the deliverance of any faculty unless its reliability is proven in advance, is irrefutable (Inq. 5.7, p. 71; cf. IP 6.5, p. 480). We cannot *show* that he or she is wrong without assuming something he or she would question.

But perhaps, for all that, we may *know* that he or she is wrong, if Reid's externalist approach to epistemology is correct.

CAUSATION AND FREEDOM

As noted above, Reid thinks we have many conceptions, such as that of a self or subject of mental operations, that we could not have on Humean principles. Among them is the conception of active power, or real efficacy in bringing about changes, to which Reid turns in his third book. He thinks we obtain a clear conception of such power when we are conscious of our own activity in bringing something about by an act of will. Active power is exercised only by agents or substances, not by events, so in the strictest sense of causation, only agents are causes for Reid. When we speak of one event causing another, Reid tells us, it would be more proper to speak of events related by lawful sequence or a relation of sign and thing signified.

That we sometimes act freely (or that we possess "moral liberty") is, according to Reid, a natural conviction, comparable to our belief in a material world. In the *Active Powers*, he offers three arguments that we really do possess such liberty. The first is based on the "naturalness" of our conviction in regard to it, the second on the notion of moral responsibility, and the third on our ability to secure ends by prosecuting a long series of means.

Reid rejects accounts of moral liberty such as those of Hobbes and Hume, who seek to make liberty compatible with determinism. He would reject Hume's suggestion that I did A freely if I did A as a result of willing to do it and would have done otherwise if I had willed otherwise. In a universe in which my willing was itself the end of a causal chain stretching back to the Big Bang, the conditions of this definition might be satisfied, yet I would not, according to Reid, have acted freely. It is a further requirement of liberty that my willing not have been determined by antecedent events in that way. But that is not to say that my willing must be random or uncaused. On the contrary, in a case of free action, it is caused by *me*, the agent. In this way Reid brings his theory of agent causation into his account of liberty, attempting to escape the dilemma that has determinism as one horn and arbitrary uncaused acts of will as the other. Reid believes that every event has a cause, but he holds that the cause of an event need not be another event—it may be an agent.

Agent-causation theories of human action inspired by Reid began to undergo a revival during the last third of the twentieth century, finding advocates in Roderick Chisholm and Richard Taylor, among others. Such theo-

ries offer a tantalizing glimmer of hope for resolving old problems yet face formidable problems of their own. If I am the cause of my willing to do A, mustn't there be such an event as my causing the willing? If so, what is the cause of *that* event? If it is *nothing*, we have fallen back on the randomness horn and violated Reid's professed belief that every event has a cause. If it is a *further event*, we are back on the horn of determinism. If it is the *agent*, we have taken the first step of an infinite regress in which I am the cause of my willing A, the cause of my causing of my willing A, and so on, *ad infinitum*.

MORAL PHILOSOPHY

Reid is often considered to be a member of the moral-sense school of philosophy, insofar as he holds that moral notions and moral determinations are the product of a moral faculty or sense. He insists, however, that the employment of the term *sense* is accurate only with the proviso that a sense can deliver judgments as well as feelings. In opposition to Hume, he holds that "moral approbation implies a real judgment" (AP 5.7, pp. 457–481), capable of being true or false, and is not merely an expression of feeling like "Hurrah!" (It must be said, however, that his criticisms of Hume sometimes convert the supposedly noncognitivist view he is attacking into a subjectivist form of cognitivism). In further opposition to Hume, he holds that reason is not merely the slave of the passions but has a real role to play in the selection of ultimate ends of action (AP, 5.3).

Reid also opposes another kind of view that sometimes goes under the rubric of moral-sense theory: the view that moral properties are analogous to secondary qualities, as in the suggestion that for an action to be right is for it to arouse favorable moral emotion in those who contemplate it. Reid protests that such accounts abolish the necessity of moral principles. It is necessary, according to him, that actions of certain types are right but contingent that they produce whatever effects they do in those who contemplate them (IP, 6.6, pp. 494–495). On the whole, Reid's views probably bear less resemblance to moral-sense theories than they do to the intuitionism of G. E. Moore. Much of what Reid says about *right* anticipates what Moore said about *good*: that it is indefinable, that we understand what it is by an original power of the mind, and that our moral faculty provides us with first principles about which types of acts are right and which wrong.

REIMARUS, HERMANN SAMUEL (1694–1768)

Hermann Samuel Reimarus, the German philosopher and theologian, was born in Hamburg and studied theology at Jena. After serving as a lecturer in Wittenberg and as director of a high school in Wismar, he became a teacher of oriental languages at the Johannes-gymnasium in Hamburg. He began writing very late in life, when he was about sixty. One of his most important works, *Apologie oder Schutzschrift für die vernünftigen Verehrer Gottes* (Apology for or Defense of the Rational Worshiper of God), was first published by Gotthold Ephraim Lessing—posthumously and only in part—as fragments of an allegedly anonymous manuscript found in the Wolfenbüttel Library, where Lessing was librarian ("Wolfenbüttler Fragmente eines Ungenannten," in *Beiträge zur Geschichte und Literatur, 1774–1777*).

Reimarus was originally a Wolffian, and Wolffianism was a lasting foundation for his thought; but he developed individual doctrines in both philosophy and theology as one of the "popular philosophers." He stressed the moral aim of philosophy, that is, the happiness and moral perfectibility of man. He dissented from Christian Wolff chiefly in his views of philosophical methodology. He wrote in a "popular," or nonscholastic, style; he asserted that philosophy can be neither as certain as mathematics nor mathematically demonstrated; he stressed the func-

tion of common sense in knowledge; and he tried to simplify logic. In metaphysics, his main points of divergence from Wolff were his admission of a real interaction of soul and body and his view that life cannot be mechanically explained, but that it is an effect of the soul.

Reimarus's most important work was in the field of animal psychology and in his classification of the instincts of animals. Humans, unlike animals, have only a very few instincts. This lack may be a disadvantage for material life, but it is the basis for morality.

Reimarus appeared in his lifetime to be a moderate advocate of natural religion who did not openly oppose Christian revelation. But in the posthumous *Apologie* he submitted Christian revelation to a radical criticism in the spirit of English deism. In this work, for the first time in Germany the traditional view of Christianity was attacked neither on a speculative plan nor through superficial historical arguments, but on the basis of sound historical scholarship. Reimarus pointed out discordances between the Old and the New Testaments and between the different sections of each. He refused to accept the Gospels as the word of God, but described them as being an exposition of theological views elaborated by Jesus' successors in the leadership of Christianity. He considered the accounts of miracles, and in particular the account of the resurrection of Jesus, to relate events that never happened and to be forgeries of the Apostles. This purely rationalistic criticism made a tremendous impression on late eighteenth-century Germany, and deeply influenced the subsequent evolution of German theology.

REINCARNATION

The doctrine variously called transmigration of souls, metempsychosis, palingenesis, rebirth, and "reincarnation" has been and continues to be widely believed. Although some of these terms imply belief in an immortal soul that transmigrates or reincarnates, Buddhism, while teaching rebirth, denies the eternity of the soul. The word *rebirth* is therefore the most comprehensive for referring to this range of beliefs.

In one form or another the doctrine of rebirth has been held in various cultures. It was expressed in ancient Greece (Pythagoras, Empedocles, Orphism, Plato, and later, Plotinus); among some Gnostics and in some Christian heresies such as the medieval Cathari; in some phases of Jewish Kabbalism; in some cultures of tropical Africa; and most notably in such Eastern religions as Jainism, Buddhism, Hinduism, and Sikhism. Some European philosophers, notably Arthur Schopenhauer and J. M. E. McTaggart, have incorporated the doctrine into their metaphysics. The origin of the doctrine of rebirth as a religious belief is obscure. There is evidence, both in Greece and India, that it was not characteristic of early Aryan cultures. It is virtually certain that in India it goes back to prehistoric times; it was then taken up by Brahmanic religion and appears as a new doctrine in the Upaniṣads.

Views vary about the scope and mechanism of rebirth. It is part of Indian thought, for instance—but not of African beliefs—that men can be reborn as animals and even as plants (not to mention as gods and spirits). Rebirth can take place not merely on Earth but also in a multiplicity of heavens and purgatories. Thus, although the prevalent belief is that rebirth occurs immediately upon death, this does not entail immediate earthly reincarnation, a feature that helps to make rebirth theory incapable of empirical disproof. In the Buddhist *Tibetan Book of the Dead*, however, a transitional period (*bardo*) of forty-nine days between death and rebirth is postulated. During this state the individual is translated to a

realm where he perceives the divine secrets; for the impure, these are so frightening that they flee back to earth and are reborn.

In Indian thought, there is a fairly large amount of speculation about the embryological mechanics of rebirth. Thus the Sāṃkhya school of Indian philosophy holds that the mental aspect of a person bears the impression of previous deeds (karma) and that it accordingly becomes associated with a particular fetus. But since during the period of fetal development the growing body is not capable of supporting the mental aspect, a “subtle” (unobservably refined) body is postulated. Thus the continuous element throughout rebirth and until liberation is the mental aspect associated with the subtle body.

In Buddhism it is held that the fetus results from the interaction of the sperm and material in the mother. These combine in a suitable way when associated with conscious states, as a further element in the process, to produce the right sort of individual to fit previous karma. Broadly speaking, then, rebirth theory implies that the genetic endowment of a person does not fully determine his early development but that a mental or spiritual factor associates itself with a suitable organism at conception. Thus karma is often taken to function through the homing of a soul upon a morally and physically appropriate fetus. McTaggart, in urging this, uses the analogy of chemical affinities.

A number of arguments in favor of the theory have been propounded; they can be classified as metaphysical, empirical, and theological. It is convenient to record here those arguments that do not depend too closely on metaphysical conclusions peculiar to particular philosophers, such as the argument for rebirth as accounting for knowledge of the Forms, as in Plato, and the complex metaphysical argument in McTaggart that depends in part on his theory of causation.

In Indian sources, two main metaphysical arguments have been employed. It may be noted that there has been relatively little explicit discussion of the issue in Indian philosophy, since no school was concerned with denying the doctrine, except the Materialist school, which was extinct by medieval times. (1) A Buddhist argument can be expressed as follows. All states have prior causes; some conscious states are not caused by bodily states; therefore the first physically uncaused state of an individual must have a prior nonphysical cause. But the existence of God is not admitted; hence there must be an empirical conscious state prior to conception and birth. This argument applies indefinitely in a backward direction through previous births. (It may be noted that the argument is con-

sistent with the Buddhist denial of an eternal soul, since the mental states of an organism are no more permanent than the physical ones.) (2) There is a Hindu argument from the eternity of the soul, which has been used in modern times by Radhakrishnan. Souls are eternal, but the normal condition for a soul is to be associated with a body. Hence it is likely that the soul in the past and future has a virtually everlasting succession of bodies. Thus metaphysical arguments attempting to establish the eternity of the soul have been taken to imply preexistence as well as postexistence.

Empirical arguments are as follows. (3) Children have instinctive capacities, which suggests that there must be learning prior to birth. Similarly, it is sometimes argued that child geniuses, such as Wolfgang Amadeus Mozart, indicate prenatal training. (4) Some people claim to remember past births, as in the case of Bridey Murphy. This claim is commonly made in the East for yogis and persons of deep spiritual insight, such as the Buddha and Buddhist saints. (5) The *déjà vu* experience and claims to knowledge of people and places that are not based on previous experience in this life have been cited as indicating rebirth. A counterargument is used against the objection that most people have no memories of such previous lives: Death is a traumatic experience (and so is birth), likely to cause amnesia. (6) The soul is indivisible and thus cannot derive from the parents, since it would then have to be a combination of parts.

The three important forms of theological argument are as follows. (7) Hindu and other scriptures and theologians are reliable in other matters and so ought to be reliable with respect to the teaching of rebirth. (8) Rebirth, associated with karma, provides a solution to part of the problem of evil, since inequalities and sufferings are the result of people’s past deeds. (9) The doctrine of rebirth provides the possibility of a long process of self-perfection, which harmonizes well with the religious vision of the world as a theater for moral striving.

The following are the objections that have been or can be brought against the arguments for reincarnation. Three objections to argument (1) are, first, the concept of emergent characteristics obviates the difficulty in explaining the cause of psychical states, although perhaps at the expense of being obscure. Second, the first premise (that all states have prior causes) is arguable, and it might be that nonphysically caused mental states are simply not caused. Third, the existence of God cannot be ruled out. (2) The plausibility of the argument depends on the plausibility of arguments for the eternity of the soul. Further, in Indian religious thought there is the possibility of

mokṣa, or *nirvāṇa*, a state of liberation in which there is no more rebirth. Consequently, it is inconsistent to hold that embodiment is necessary to souls. The Buddhist denial of a permanent self occasioned the criticism that there is nothing carried over to another life that would ensure individual continuity—the reply being that, on the Buddhist analysis, the individual in his present life is only a series of events, so that there is no essential difference in considering a succession of lives as constituting an individual series.

The following are objections to the empirical arguments. (3) Modern biology can sketch alternative explanations of instinct and genius in children. (4) Although some people seem to remember past lives, the evidence is not so unambiguous as to be conclusive; and if saintliness is a condition for remembering previous births, it would be difficult to verify such a memory—it would be hard to conduct an “experiment” in becoming a saint. (5) Similar problems arise with the evidence of *déjà vu* experiences. As to whether death is a traumatic experience, there is no evidence. (6) The creation of souls by God is compatible with the argument concerning the indivisibility of the soul; but in any case the argument depends on a soul-body distinction that may not be acceptable.

The objections to theological arguments are the following. (7) The validity of particular scriptures and theologies on matters of detail is especially suspect. (8) The argument that rebirth explains the existence of evil could not by itself be conclusive, since the problem of evil exists only for those who believe in a good God. (9) A similar consideration applies to the argument that rebirth allows the possibility of self-perfection.

Although believers in rebirth have scarcely touched on the matter, the theory of evolution also presents considerable difficulties to the traditional doctrine of a virtually infinite series stretching back into the past. In Indian mythological cosmology, however, there are periodic destructions of the cosmos, and during these periods embodied souls continue to exist latently; no doubt a similar assumption may deal with the above biological difficulties by arguing that before the emergence of life, souls existed latently, or in other parts of the cosmos. The problem remains, however, that this account would not be easily, if at all, checked by empirical evidence.

The hypothesis of reincarnation presents interesting problems about personal identity. If personal identity is analyzed in terms of memory, there would seem to be only a vacuous distinction between saying that *A* is reborn as *B* and that *A* and *B* are separate persons. C. J. Ducasse, however, has argued (*A Critical Examination of*

the Belief in a Life after Death, p. 225) that memory of any given life may be regained at some time or other in the series, and this would hold the series together. If bodily identity were held to be necessary to personal identity, rebirth could scarcely be meaningful, as it involves causal action at a distance in the transition from *A*'s death to *B*'s birth or conception.

Bibliography updated by Christian B. Miller (2005)

REINHOLD, KARL LEONHARD (1758–1823)

Karl Leonhard Reinhold, the Austrian philosopher, was educated by Jesuits until the dissolution of their order in 1773, when he entered the Catholic college of the Barn-

abites, where he also taught, from 1778 to 1783. In 1783 Reinhold left Vienna for Leipzig and in the same year abandoned Catholicism in favor of Protestantism. A year later he moved to Weimar, where he was invited by Christoph Martin Wieland to contribute to his *Teutscher Merkur*. Soon he was not only Wieland's closest friend but also his son-in-law. Reinhold's first article, "Gedanken über Aufklärung," in which he traced the emergence of Enlightenment thought, appeared in July 1784, just a few months before the publication of Immanuel Kant's famous essay "What Is Enlightenment?" In his article Reinhold pleaded for the fuller realization of such. Enlightenment aims at greater tolerance toward religious minorities, more widespread secularization of knowledge and its greater accessibility to all sections of the population, and, above all, for the right of the individual to seek and assert truth free from fear, according to his critical reason and moral convictions.

Although two years later (1786) he was to publish a series of articles in support of Kant's critical philosophy, his second article in the *Merkur* (1785) was directed against Kant's unfavorable review of Johann Gottfried Herder's *Ideen*. The article appeared anonymously, but Reinhold later admitted his authorship to Kant. The articles dealing with Kant's *Critique of Pure Reason*, published under the title "Briefe über die Kantische Philosophie" from 1786 to 1787, established Reinhold's reputation as the most skillful exponent of Kant's philosophy and resulted in his being offered the chair of philosophy at the University of Jena in 1787. Reinhold was no less successful as a university teacher, and soon after his arrival Jena became one of the chief centers of Kantian studies. He attracted many students to Jena, and so great was his popularity that he was repeatedly urged to refuse the appointment offered him at the University of Kiel. Reinhold hesitated at first but eventually decided to move to Kiel in 1794, where he remained until his death.

One of the reasons for his departure, perhaps the most decisive, is revealed in a letter to Wieland that Reinhold later published in a selection of essays (*Auswahl vermischter Schriften*, Jena, 1796), under the title "Ueber die teutschen Beurtheilungen der französischen Revolution." Reinhold became increasingly worried over his countrymen's reactions to the excesses of the French revolutionary tribunals. In Kiel, which was then under Danish rule, he hoped to find a calmer political climate. Without condoning the terror of the revolutionaries, he nevertheless deplored the inferences that were drawn from it by leading public figures in Germany. In particular he viewed with anxiety the introduction of repressive measures and

the tendency to regard the French Revolution as a conspiracy of the philosophers. The French revolutionaries, he argued, may have been mistaken in attempting to deduce political rules from abstract principles that were often inadequately understood, but they were correct in their assessment of the desperate plight of their compatriots. If inferences were to be drawn, these would not suggest that philosophy presented a danger to orderly government but rather that disorderly government encouraged men to invoke philosophy in a manner unwarranted by its inherent limitations. Practical considerations such as these, no less than more strictly theoretical ones, prompted Reinhold to inquire more closely into the nature and scope of philosophical speculation.

Most of the works that he wrote at Kiel advanced a "fundamental philosophy" concerned with the basic presuppositions of scientifically valid thought. As the basic axiom of his "fundamental philosophy" Reinhold postulated the principle of consciousness, which he formulated in this way: By virtue of consciousness the perceiving (*erkennende*) subject is capable of distinguishing himself as something distinct from, while at the same time related to, the object of his consciousness, which, however, is not the object itself but rather the idea or notion (*Vorstellung*) of it. The consciousness itself constitutes a basic and irreducible fact, capable of neither proof nor further definition. It can only verify itself by reflecting upon itself. Reinhold was anxious to demonstrate that every thought process involves both a priori and a posteriori elements. The relation of the *Vorstellung* to the external object embodies its a posteriori material content (*Stoff*), whereas the subjective activity involved (*Vorstellungsvermögen*) in shaping the material content into a clear *Vorstellung* constitutes its a priori form (*Form*).

Reinhold stipulated three interconnected stages in the operation of consciousness: sense perception (*Anschauung*), which he classified as a receptive activity, and cognitive understanding (*Verstand*) and reflective reasoning (*Vernunft*), both of which he described as spontaneous activities. The product of these combined activities is the *Vorstellung*, which, Reinhold warned, must not be confused with an "image" or an "impression," for both terms suggest mere receptivity. Nor must it be identified with a "representation" of the object, since there is no way of either proving the identity of the *Vorstellung* with the object or even of comparing its similarity to the object. It follows that the object as such, no less than the subject as such, remains not only unknowable (as Kant realized) but also inconceivable. Both subject and object, therefore, as things-in-themselves are

pure abstractions. They are the residue of a *Vorstellung*, the thing minus the notion or conception of it.

Without denying the existence of things-in-themselves, Reinhold refused to commit himself as to the nature of their existence. He explicitly stated that he was merely anxious to determine the possibility and the limitations of cognition, not to inquire into its psychological origins or into the ontological nature of the objects of cognition. His declared aim was to provide a descriptive account, a phenomenology, rather than a theory of cognition, together with an analysis of the terminology commonly employed in this field. In spite of, or perhaps because of, Reinhold's deliberate delimitation of his theoretical undertaking, his works provided suggestively fertile starting points for subsequent Kantian research from Johann Gottlieb Fichte to Arthur Schopenhauer.

RELATIONS, INTERNAL AND EXTERNAL

Common sense would seem to hold that if some properties of a thing were taken away from it, it would no longer be the same thing. Further, it seems to hold that this is not the case for all properties of the thing. This intuition is the basis of the distinction between essential and accidental properties of a thing. It is also the basis of the distinction between the internal and the external relations that that thing bears to other things. For if among the properties that are essential to a thing (for example, the state of Maine) are relational properties, properties whose characterization essentially involves reference to some other thing (for example, the property of being north of Boston), then we say that the relations in question (for example, the relation between Maine and Boston) are *internal* to that thing (Maine). If we think that the thing would be the same were it (for example) not north of Boston—as in the case of a railroad car traveling through Maine—then we say that the relation in question is merely *external* to that thing.

The most familiar sort of relations considered when the topic of internal relations is discussed are relations between two or more particulars. However, the same internal–external distinction may be drawn in the case of relations between universals and particulars and also in the case of relations between two or more universals. If one holds that for every property *P* that a particular *X* displays, there is a universal, *P*-hood, to which *X* stands in the relation of "exemplification," then *all* of *X*'s properties may be construed as relational properties. Some of these relations of exemplification may be regarded as internal to *X* and others as external. Again, one may say that a universal such as "manhood" stands in an internal relation to certain other universals (for example, "rationality") and

in an external relation to other universals (for example, “philosopherhood”). Here the internal relation in question will be entailment, in the sense of “entails” in which we say that a given property (“being a man”) entails another property (“being rational”). In what follows, however, we shall confine ourselves as far as possible to relations holding between particulars, both because the philosophical literature has focused on such relations and because the notions of “exemplification of universals” and of “relations of entailment holding between universals” are sufficiently obscure and controversial to require detailed supplementary discussions. (Also, we shall not always trouble to distinguish between discussion of internal *properties* and of internal *relations*, since whatever doctrine a philosopher holds about the former will apply, *mutatis mutandis*, to the latter).

Two extreme positions have been put forward by philosophers who regard the internal-external distinction as unclear or incoherent. The first is that all of a thing’s properties are essential to its being what it is (and, a fortiori, that all its relations are internal to it). This position is associated with idealism and monism, for reasons that will emerge as we proceed. It holds that the connections between each of a thing’s properties (including its relational properties) and all of its other properties are so close that the deprivation of a single property would force us to say that, in a nontrivial sense, the thing is no longer what it was.

The second extreme position holds that none of a thing’s properties are essential to it (and thus, a fortiori, that no relations are internal to it). This view is put forward by those who make a firm distinction between the thing itself and a description of it. These philosophers say that, although certain properties of the thing are such that a given description could no longer be correctly applied to it were these properties absent, the notion that “the thing would no longer be the same” if these properties were absent is either trivial or misleading. For, in the weakest sense of “same,” the absence of any of its properties would make the thing no longer the same. Any stronger sense will, however, equate “being the same thing” with “being such that a given description correctly applies to it.” But since for each thing there are an infinity of equally correct descriptions, and nothing in the thing itself determines which of these is the description, any specification of “essential properties” will be arbitrary.

Both positions hold that the traditional essence-accident distinction, which is drawn by common sense and was first formulated explicitly by Aristotle, must be aban-

doned. The second position holds that the notion of “essential property” must be seen as a purely conventional notion, without a ground in the nature of the thing itself. It therefore suggests that we replace the notion of a relation being internal to a thing with the notion of a given relational description of a thing (such as “being north of Boston”) being internal to (that is, a necessary condition of) another description of the thing (such as “being in Maine”). The first position holds that the notion of “essential property” suggests, wrongly, that there is such a thing as a nonessential property. But since omniscience would see the universe as a seamless web (and, perhaps, as one single individual thing—the Absolute), this suggestion is misleading. Granted, they may say to representatives of the second position, that our present notion of “essential property” is a merely conventional one, we should not be led to conclude that things have no intrinsic natures. They do have intrinsic natures, but these can be known only *sub specie aeternitatis*, as facets of the Absolute. The commonsense essence-accident distinction is natural and inevitable, given the imperfect state of our knowledge. For omniscience, however, this distinction would be pointless.

This brief sketch of the opposing positions suffices to suggest how intimately the issues about internal relations are bound up with a whole range of other philosophical problems—problems about the notions of substance, of essence, and of “bare particulars,” about “real” versus “nominal” definitions, about nominalism versus realism, about the way in which we refer to and identify particulars, and about the nature of necessary truth. It is perhaps not too much to say that a philosopher’s views on internal relations are themselves internally related to all his other philosophical views.

THE VIEW THAT ALL RELATIONS ARE INTERNAL

The view that all relations are internal, in the form in which it has been discussed in the twentieth century, originated in the writings of the absolute idealist school in England and America in the period 1890–1920. In various forms it was held by F. H. Bradley, Josiah Royce, Bernard Bosanquet, and many others. Its most recent sustained defense is found in the work of Brand Blanshard, a follower of Bradley, notably in *The Nature of Thought* (1939). It has obvious historical connections with the doctrines of the seventeenth-century rationalists, notably Gottfried Wilhelm Leibniz’s view that all truths are analytic and Benedict de Spinoza’s assimilation of causal relations to logical relations. Its most important historical

antecedent, however, is the philosophy of G. W. F. Hegel. Hegel's insistence that the world was rational through and through, because Reason (or "Spirit") alone was real, was the principal inspiration of the philosophers who adopted the view that all relations were internal. For, if some relations were external, then the universe would be "impenetrable" to reason, in the sense that there would be brute particular facts not deducible from universal truths even by God himself.

A. C. Ewing, in *Idealism* (1934), provides a comprehensive account of the various meanings given to the term *internal* by exponents of absolute idealism and a critical analysis of those arguments in favor of the doctrine that all relations are internal that depend upon an ambiguous use of "internal." As Ewing points out, the meanings given to "internal" ranged from a very weak sense, in which to say that the relation *R* which *X* bore to *Y* was internal to *X* meant merely that "*R* makes a real difference to *X*," to a very strong sense, in which it meant that "from a knowledge of *Y* and *R* we could infer with logical necessity that *X* possesses a certain determinate or relatively determinate characteristic other than the characteristic of standing in the relation in question." Because such ambiguities permeate the discussion of the topic in such writers as Bradley and Royce, we shall not attempt an exegesis of their arguments. Instead, we shall attempt a reconstruction of two particularly persuasive arguments that seem to represent at least part of the common core of the absolute idealists' defense of their position on this subject. The two arguments to be examined by no means exhaust the repertoire of arguments that have been deployed in favor of the view that all relations are internal, but they are the arguments on which criticism of this view has chiefly centered.

ARGUMENT FROM THE NATURE OF SELF-IDENTITY. The first argument, which will be called here the argument from the nature of self-identity, was first clearly formulated by a critic rather than a proponent of the view that all relations are internal. G. E. Moore, in a classic attack on this view ("External and Internal Relations"), suggests that "one thing which is always implied by the dogma that 'All relations are internal' is that, in the case of every relational property, it can always be truly asserted of any term *A* which has that property, that any term which had not had it would necessarily have been different from *A*." The argument in favor of this view is simply that, as Moore puts it, "if *A* has *P*, and *x* has not, it *does* follow that *x* is other than *A*." In other words, it is unquestionably true that

- (1) *A* has *P* entails that (*x* does not have *P* materially implies that *x* is other than *A*).

Contemplation of this truth, Moore suggested, led philosophers to say that "*A* could not be what it is (but would necessarily be something different) did it not have *P*."

Now, as Moore points out, the argument as it stands is fallacious. (1) does not permit the conclusion that

- (2) *A* has *P* materially implies that (*x* does not have *P* entails that *x* is other than *A*).

Only (2) would permit the conclusion that *A* would necessarily be a different particular did it not have *P*. The difference between (1) and (2) may be put by saying that all that (1) tells us is that *A* cannot both have and not have the property *P*, whereas (2) tells us that *A* could not be *A* unless it had *P*. (1) is trivial, whereas (2) blurs the commonsense contrast between essential and accidental properties (and thus between internal and external relations). As Moore puts it, "(1) asserts that if *A* has *P*, then any term which has not, *must* be other than *A*; (2) asserts that if *A* has *P*, then any term which had not, would necessarily be other than *A*." Moore notes that to confuse the two propositions, "you have only to confuse 'must' or 'is necessarily' with 'would necessarily be.'" This confusion, in turn, will lead one to confuse the (physically necessary but logically contingent) fact that *A* has *P* with a statement about what is *logically* necessary for something to be *A*. While not attempting to cite examples of this fallacy in the writings of the absolute idealists, Moore claimed that much of their willingness to adopt the view that all relations are internal was due to their having confused (1) and (2). Whether or not this fallacy played the role in their thought that Moore thought it did is less important, from a historical point of view, than the influence exercised by Moore's diagnosis. Philosophers in general tended to agree with Moore that the absolute idealists had been guilty of this confusion, and his essay was a turning point in discussion of the topic. Defenders of the thesis of the internality of all relations who came after Moore were forced to produce arguments against the main presupposition of Moore's argument—that the commonsense distinction between logically contingent propositions and logically necessary propositions was unobjectionable. Crudely put, one may say that before Moore's essay, defenders of the view that all relations were internal felt able to argue that simple reflection on commonsense criteria for self-identity led to the conclusion they desired. After Moore's essay, they were forced to attempt to undermine common sense by claiming that the distinctions

Moore had drawn were, though commonsensical, philosophically indefensible.

ARGUMENT FROM THE NATURE OF CAUSALITY. The above was the strategy adopted by Blanshard in his *The Nature of Thought*, in which he presents the second, far more important and profound, argument in favor of the doctrine that all relations are internal. This may be called the argument from the nature of causality. Moore, like most philosophers in the tradition of British empiricism, had taken for granted a distinction between physical necessity and logical necessity, a distinction between the sense in which it is necessary, given the laws of nature and the past history of the universe, that a given particle be located at a given point in space at a given time, and the sense in which it is not necessary, *simpliciter*. Traditional rationalism, on the other hand, had questioned this distinction. Although earlier absolute idealists had also rejected the distinction between two kinds of necessity, they had done so *en passant*. They had treated it as simply one more consequence of empiricism's uncritical acceptance of a commonsense metaphysics that, they claimed to have shown, was fundamentally incoherent. Blanshard, approaching the matter epistemologically rather than metaphysically, brought forward a battery of arguments designed to show that the acceptance of this distinction was the result of a mistaken Humean analysis of knowledge. By weakening this distinction and claiming that causal necessity (by virtue of which *A* had *P*) could not be separated from logical necessity (by virtue of which *A* was self-identical), he was able to argue that what Moore had viewed as a simple confusion was at worst a confused formulation of a vitally important insight.

In examining this second argument, it will again be convenient to look to its critics rather than to its defenders. Ernest Nagel, in a critique of Blanshard's *The Nature of Thought* titled "Sovereign Reason," restates and criticizes Blanshard's views on internal relations in a way that brings out very clearly their connection with Blanshard's treatment of causality. Blanshard, in turn, has replied to Nagel in the later chapters (particularly Ch. 12) of his *Reason and Analysis* (1963). A summary of the Blanshard-Nagel controversy will serve two purposes. It will trace the most recent line of defense adopted by defenders of the view that all relations are internal, and it will lead us to an understanding of why some philosophers claim that no relations are internal.

Blanshard puts forward, and Nagel quotes as a basis for criticism, the following version of the doctrine that all

relations are internal. Despite the ambiguities detected by Ewing, Blanshard holds that "the principal meaning" of this doctrine is clear and formulates it as follows:

- (1) that every term, i.e., every possible object of thought, is what it is in virtue of relations to what is other than itself;
- (2) that its nature is affected thus not by some of its relations only, but in differing degrees by all of them, no matter how external they may seem;
- (3) that in consequence of (2) and of the further obvious fact that everything is related in *some* way to everything else, no knowledge will reveal completely the nature of any term until it has exhausted that term's relations to everything else. (*Nature of Thought*, Vol. II, p. 452)

Nagel notes, and Blanshard would agree, that everything here turns on the notion of the "nature of a term." If the term's nature includes all its properties, then Blanshard is right. Nagel bases his general objections to Blanshard on the claim that this is a perverse use of "nature," since "it is quite clear that just what characters are included in an individual, and just where the boundaries of an individual are drawn, depend on decisions as to the use of language. These decisions, though motivated by considerations of practical utility, are *logically arbitrary*" (p. 275). Nagel, in other words, is saying that "the nature of *X*" consists of just those properties of *X* whose absence would cause us to cease using "*X*" to refer to *X* and that the selection of these properties is determined not by empirical study but by convention. The list of such properties is finite, whereas the list of the properties of *X* is potentially infinite. Nagel thus adopts what has become the standard empiricist view, first clearly formulated by A. J. Ayer in "Internal Relations," that to determine which properties of *X* are internal to it is merely a matter of determining which propositions about *X* are analytic and that determining *this* is simply a matter of consulting linguistic usage. To urge that the nature of a thing includes all its properties would, given this view, be to urge that *all* propositions about *X* are analytic. Both Nagel and Ayer treat this conclusion as a *reductio ad absurdum*.

In examining Blanshard's arguments, Nagel first takes up Blanshard's form of the argument from the nature of self-identity and disposes of it by drawing what is essentially Moore's distinction between the logically contingent fact that *A* has *P* and the logically necessary fact that anything that does not have *P* cannot be identical with *A*. His defense of this distinction is simply that unless the distinction is drawn, we shall wind up with the view that "the nature of *X*" is identical with *X* itself and

thus that “the nature of a thing, like the thing itself, would be something that is in principle indefinable and could not therefore be made the basis for bringing into systematic order any of the characters which the thing displays” (p. 276). But from Blanshard’s point of view, this reply begs the question, since Blanshard would be quite willing to say that the nature of any given particular is indeed indefinable (by finite minds). For Blanshard the question is merely pushed back to the issue of whether a satisfactory epistemology can be constructed on the basis of the view that all logical necessity has its source in linguistic convention. But this latter issue is just the issue of whether causal relationships (which are agreed on all sides to be matters not of convention but of empirical inquiry) can, in the last analysis, be held to be distinct from logical relationships. If they cannot, then it would seem fair to say that although we must (unfortunately) work with the commonsense distinctions between necessary and contingent truths, essence and accident, physical and logical necessity, and the like, these distinctions are nevertheless mere pragmatic makeshifts (pertaining, in Bradleian terminology, to Appearance rather than to Reality). To invoke them is to attend not to how things are but merely to how we are forced (by the limitations of our minds and of our everyday language) to talk about them.

Thus the battle between Blanshard and Nagel is truly joined only when Nagel takes up the question whether “logical necessity is involved in causal relations.” Blanshard has, as Nagel notes, two principal arguments for the view that it is so involved. The first is that causal relations must be analyzed either in terms of “mere regularity of sequence” or in terms of “entailment.” The failure of the regularity view will, in Blanshard’s eyes, constitute a proof of the entailment view. But the entailment view is just that “*A* causes *B*” is a statement about a logical relation between *A* and *B*. Now if (as is not implausible) all true relational propositions about particulars are propositions that are true in virtue of causal relations between the particulars mentioned in these propositions, then it follows that all particulars are connected to all others by logical relations and that every such proposition would be seen (by omniscience) to entail a logical truth about every such particular.

Nagel has two objections to this argument. First, the “regularity” and “entailment” views do not exhaust the available analyses of causality; second, “the entailment view contributes *nothing* toward advancing the aims of specific inquiries into the causal dependencies of physical nature.” The second objection can be dismissed by Blan-

shard as irrelevant, since he is quite willing to admit, with David Hume, that observation of regular sequence is our only method for determining what causal relations actually hold (except, perhaps, in the case of “direct insight” into certain relations between mental states or events). Blanshard need merely insist that regularity provides evidence of an underlying entailment but that the regularity and the entailment must not be confused. Blanshard offers no reply to Nagel’s first objection, but one suspects that he would argue that all proposed *via media* analyses of causality in fact boil down to one of the two alternatives he has suggested. Even if this point is granted to Blanshard, however, the whole question of the validity of his attack on the regularity theory remains. We must leave the topic with the remark that Blanshard can, in attacking this theory, take full advantage of the embarrassment encountered by Rudolf Carnap, Nelson Goodman, and others in their attempts to construct an inductive logic on the basis of Neo-Humean “regularities.” Further, recent work in inductive logic (such as Goodman’s *Fact, Fiction and Forecast*, 1955) and the philosophy of science (the work of Hilary Putnam, Wilfrid Sellars, P. K. Feyerabend, and others) has made it apparent that the distinction between matters of convention and matters of fact is not so clear as Hume and the early positivists believed. This recent work is closely connected with W. V. Quine’s skepticism about the analytic-synthetic distinction and related work in the philosophy of language. It is perhaps not too much to say that empiricism is presently in a state of crisis and that the crisis revolves precisely around the validity of the distinctions that empiricists have traditionally invoked against the thesis of the internality of all relations. We must conclude that the question of the validity of Blanshard’s first form of the argument from the nature of causality must remain undecided until these issues have been further clarified.

Before leaving the Blanshard-Nagel controversy, however, we must take up the second of Blanshard’s arguments in favor of the view that logical necessity is involved in causation. This argument is that philosophical reflection upon the nature of causality leads us to conclude that

to say that *a* produces *x* in virtue of being *a* and yet that, given *a*, *x* might not follow, is inconsistent with the laws of identity and contradiction. Of course if *a* were a cluster of qualities abstracted from their relations, and its modes of causal behaviour were another set conjoined with the former externally, then one could deny the latter and retain the former with perfect con-

sistency. But we have seen that when we say *a* causes *x* we do *not* mean that sort of conjunction; we mean an intrinsic relation, i.e., a relation in which *a*'s behaviour is the outgrowth or expression of *a*'s nature. And to assert that *a*'s behaviour, so conceived, could be different while *a* was still the same would be to assert that something both did and did not issue from the nature of *a*. (*Nature of Thought*, Vol. II, p. 513)

With this argument, as Nagel notes, we are back at the perplexing notion of "the nature of *a*." Whereas the entailment analysis of the nature of causation can perhaps be stated without using the notion of the "nature of *A*" (although if it were, it might be difficult for Blanshard to infer the thesis of the internality of all relations from the truth of the entailment view), this present argument about the nature of causality makes essential use of this notion. At this point, therefore, Nagel returns to his general line of attack on Blanshard's formulation of the thesis of the internality of all relations and argues that what Blanshard says here is true only if "the nature of *X*" is defined as "all the properties of *X*," a definition that, in Nagel's eyes, is both idiosyncratic and such as to trivialize Blanshard's claim.

The effectiveness of Nagel's reply can be judged only in the light of a general theory about the relation between thought, language, and reality. For, here again, Nagel is taking for granted the view that whether a given property is included within a thing's nature is a question about our language, rather than a question to be settled by further inquiry about the thing itself. Just as judgment of the validity of the first form of Blanshard's argument from the nature of causality must be postponed until certain general philosophical issues have been (at least) clarified, so also judgment of the validity of the second form of this argument must be deferred until questions about the standard empiricist doctrine that all "essences" are "nominal" and that "real essence" is an incoherent notion are settled. For Blanshard can insist that Nagel has begged these latter questions. In *Reason and Analysis* we find Blanshard arguing that Nagel's view that decisions about what characters are included in an individual are "logically arbitrary" leads to the view that, for example, Socrates's snub-nosedness is as good a candidate for an essential property of Socrates as his philosopherhood. Blanshard thinks this a *reductio ad absurdum*, but this rebuttal, once again, merely moves the argument one step further back. Nagel's point is not that we arbitrarily select which characteristics of an individual shall count as essential but that the criteria of selection are pragmatic,

dictated by our present interests and the modes of classification that we have, in the past, found it convenient to adopt. Nagel would say that a choice about linguistic usage, which is, from a practical point of view, far from arbitrary, is nonetheless logically arbitrary, in the sense that a language with alternative conventions is, though inconvenient, perfectly possible.

Blanshard's basic disagreement with Nagel consists in his view that such pragmatic considerations are not the last word and his insistence that the goal of thought is the discovery of real essences. Such real essences would be discovered by discovering the chains of entailment that connect all the various universals that characterize (and, in Blanshard's metaphysics, constitute) a particular. In Blanshard's view, to say that analytic propositions are true by convention is thoroughly misleading, for such conventions are the results of attempts to discover such entailments. For Blanshard the identification of the nature of *X* with *X* itself, and of both with the totality of properties that characterize *X*, and of all of these with *X*-as-known-by-an-ideal-knower (one who could grasp the entailments between all of these properties), is not (as it is for Nagel) a series of confusions but is forced upon us by an analysis of what we mean by "knowing *X*." The validity of Blanshard's second form of the argument from the nature of causality ultimately depends upon the validity of this analysis.

UNIVERSALS. The nature and depth of the issues involved in the controversy between Blanshard and Nagel may be further clarified by calling attention to one more area of disagreement between them. This concerns the nature and knowledge of universals. Blanshard views a particular as a congeries of universals and views the internal relations between particulars as reflecting the internal relations holding between the universals that constitute them. It is almost a cliché of recent analytic philosophy that to have knowledge of a universal is simply to know the meaning of a word; thus, to be acquainted with all the universals that characterize a particular would be merely to know the meanings of all the words correctly applicable to that particular. Such knowledge would obviously fall far short of telling us about the relations in which that particular stands to other particulars. For Blanshard, however, universals have natures that are not known to those who merely know the meanings of the words that signify those universals. To know the nature of a universal "fully and as it really is" would involve knowing its relations to all the universals that are exemplified in all the particulars that exemplify the first universal.

Thus, to know any universal “fully and as it really is” would be possible only for omniscience, just as, and for the same reasons that, knowledge of the real essence of a particular would be possible only for omniscience. Thus, resolution of the controversy about internal relations would require, at a minimum, a decision concerning the adequacy of a nominalistic account of universals. Blanshard views the current antagonism toward idealism (and a fortiori toward the thesis of the internality of all relations) as largely a result of analytic philosophy’s “systematic confusion between thought and language,” a confusion that leads philosophers such as Ludwig Wittgenstein to hold (1) that the notion of having a concept or being acquainted with a universal prior to the use of language is incoherent, and (2) that the notion of detecting internal relations between universals apart from considerations of linguistic usage is a relic of a radically mistaken analysis of mental events. If these latter tenets are accepted, clearly Blanshard’s arguments cannot even get off the ground. Once again, we must conclude that the thesis of the internality of all relations cannot be profitably discussed until one has taken sides on the most fundamental issues in contemporary philosophy.

THE VIEW THAT NO RELATIONS ARE INTERNAL

When we turn to the view that no relations are internal, we turn from a controversy that reflects profound underlying disagreements concerning the analysis of knowledge to a controversy about much narrower issues concerning the analysis of naming and predication. Those who say that no particular is internally related to any other particular insist that the only entities that can be internally related to one another are characteristics of particulars. Following to its logical conclusion Nagel’s claim that the assignment of a given description to a given particular is “logically arbitrary,” they hold that to say that *X* would “not be what it is” unless it had *P* is merely to say that the particular could not be characterized in a given way unless it had this property. But since the particular is sublimely indifferent to how it is characterized, it “is what it is” regardless of whatever properties it may have. To speak of “logically necessary conditions for the self-identity of *X*” is, at best, to speak elliptically of “logically necessary conditions for correctly describing *X* as a *K*,” where “*K*” signifies some kind of thing of which *X* is a representative, or (more generally) of “logically necessary conditions for correctly describing *X* as *C*,” where “*C*” is some general characterization.

The whole notion of “properties (and, a fortiori, relations) such that *X* would cease to be what it is if they were removed” is thus either incoherent or misleading. For “being what it is” is simply too ambiguous a notion; there are indefinitely many kinds to which *X* belongs and indefinitely many characterizations that apply to it. “Being what it is” is incoherent if it suggests that one of these kinds or characterizations is *intrinsically* privileged and misleading if a user of the phrase has already picked out some such kind or characterization, thus making his choice “privileged” by stipulation. To philosophers who deny the internality of any relations, the whole notion of internal properties and relations is an unfortunate vestige of the Aristotelian notion that there are real essences of particulars to be discovered by empirical inquiry. These philosophers heartily agree with the seventeenth-century rationalists, and with Blanshard, that any Aristotelian attempt to divide intrinsically essential and intrinsically accidental properties is foolish. But whereas Blanshard, sticking to the quest for real essences, insists that this point merely shows that the real essence of an object must include *all* its properties, these philosophers take the point to show the incoherence of the notion of “real essence” and the notion of “internal property.”

It may be useful to put the contrast between the roughly Aristotelian commonsense view and the two extreme views in yet another way. If we say that common sense holds that there are both particulars and properties of particulars, then we may say that common sense holds that each particular stands in a necessary relation to some of its properties and in a contingent relation to others. Blanshard dissolves the particular into a congeries of properties, and, because he believes (a) that properties (qua universals) have intrinsic natures to be discovered by inquiry (other than inquiry into linguistic usage) and (b) that such inquiry would, in principle, discover relations of entailment between all possible properties of all possible particulars, he holds that a particular stands in a necessary relation to all its properties. Philosophers who deny both doctrines and who assert (c) that “logical necessity” can only characterize relationships between universals, naturally emerge with the conclusion that the whole notion of logically necessary relations between particulars and their properties must be discarded. To put it picturesquely, Blanshard thinks that the dissolution of the traditional essence-accident distinction leaves us with the particular as a node in a network of internal relations between universals. His opponents think that this dissolution leaves us with “bare” particulars on the one hand (particulars that could logically have any properties) and with a network of entailments between universals on the

other (a network that is, however, much “looser” than Blanshard’s, since between most universals no relations of entailment exist).

CONCEPT OF BARE PARTICULARS. As an illustration of the movement toward leaving particulars bare, we may cite Gilbert Ryle, who says, in his article “Internal Relations,” that

for this view [the thesis of the internality of all relations] to be true *or false*, it would have to be significant to predicate a logically proper name or designation of a logically proper name or designation; and it would have to be significant to assert or deny that *this* was *this*; and the question “is anything this?” would have to mean something.... “This” is not a predicate, and a sentence in which it pretends to function as one is meaningless. So there *could* be no such dispute as to whether this’s being this does or does not depend on its being in one or other of its relations. (p. 165)

This line of thought suggests the general conclusion that there are no analytic propositions that ascribe properties to particulars. For example, it is misleading to call “Socrates was a Greek philosopher” analytic, for what this statement expresses is either (1) the contingent fact that certain features (snub-nosedness, being married to Xanthippe, and so on) were compresent with certain others (being Greek, being a philosopher), or (2) the contingent fact that the word *Socrates* is used to refer to an individual who exhibited certain features.

Even among philosophers who both reject (a) and (b) and accept (c), however, this general conclusion has been a matter of debate. In what follows, we shall consider an attempt to avoid the conclusion that there can be no analytic propositions that ascribe properties to particulars and an attempt to avoid the extreme position that no relations are internal to particulars by providing a “rational reconstruction” of the commonsense view. Such attempts are motivated, at least in part, by philosophical discomfort over the notion of “bare particulars.” The nature of this discomfort may be illustrated by considering the question “What, then, *are* these particulars, apart from the properties we ascribe to them?” If particulars really are “bare,” then any answer to this question is bound to be either wrong (if it lists some features that are criteria for particularity) or unhelpful (if it consists in saying simply “Well, particulars are just the kind of thing that properties can be ascribed to”). Although the realistic bent of contemporary analytic philosophy makes

philosophers hesitate to accept the Bradleian-Blanshardian view that the whole category of (plural) “particulars” belongs to Appearance rather than to Reality, it nevertheless seems that having only bare particulars would be as bad as having no particulars at all.

INTERNAL PROPERTIES AS RELATIVE. The most explicit and comprehensive attempt to avoid Ryle’s conclusion and still retain most of his premises is found in an article by Timothy Sprigge (“Internal and External Properties”); an examination of Sprigge’s treatment of the problem will bring out the underlying issues concerning naming and predication upon whose resolution the present question depends. Sprigge notes that the strength of the Rylean position lies in the fact that

in sentences expressing particular propositions where the subject word is a name, the subject word has no connotation. Therefore no predicate word can have a connotation which is incompatible with the connotation of the subject word. But a subject-predicate sentence could only express a necessary proposition if the connotation of the subject word were incompatible with the connotation of the negation of the predicate word. ... Of course, this rests upon the questionable view that there may be naming words without connotation—and this indeed is basically the point at issue. (p. 204)

One reason why this latter point is disputable is, as Sprigge says, that “it seems that one must identify a thing by some description. Having been thus identified,” he continues, “as answering to that description, is it not in effect defined as the thing having those properties, which properties therefore it necessarily has?” (p. 205). In other words, proper names could not be used unless their users could identify their referents, and how could the users do this save by having a description in mind? Must we not say that the notion that the logician’s dogma that “proper names do not connote” is true only of such Russellian “logically proper names” as “this” (which cannot be used save in the presence of their referents)? Sprigge replies to this point by granting it but noting also that since the same particular can be identified by an indefinitely wide range of different descriptions, the point is useless if one is trying to defend the notion of internal properties. In the case of a predicate, rough agreement on criteria for its application is required if the term is to play a useful role. But there seems nothing to prevent every speaker of the language from having a different set of procedures for identifying a particular while nevertheless using the same

proper name for it. Too many connotations are, so to speak, as bad as no connotation at all for purposes of formulating necessary truths.

If we follow Sprigge here, we need not be troubled by the spectacle of bare particulars. Every particular we refer to will always be dressed in some description or other, so we need not worry about how they look when undressed. But since each particular can be dressed up in so many ways, we are as far as ever from understanding what an “internal property” might be, unless we relativize the notion and say that certain properties are internal to X relative to a person S whose personal criteria for identifying X include the presence of these properties. Relativizing the notion in this way is, in essence, the basis for Sprigge’s “reconstruction” of the notion of internal property. As a sample of the sort of intuition upon which the commonsense distinction between internal and external properties is based, he notes that even though we are driven by the Rylean reasoning outlined above to call all subject-predicate statements about particulars synthetic, we find it hard to imagine the falsehood of, for example, “Scott was, at some time in his life, a man.” But what is a synthetic proposition if not one whose falsehood can be imagined? Sprigge proposes that we simply face up to the fact that there is a class of propositions that, if we *must* choose between calling them synthetic or analytic, must be called synthetic, even though they do not have imaginable contradictories. Specifically, they are such that no program of empirical inquiry could be formulated that would lead us to decide between them and their contradictories. The point is most effectively made in the following passage:

To ask whether a thing could have been quite different, from what it is, whether Scott could actually have had all the properties of Handel, is on a different level. The questions we have just been asking are all to some degree requests for further descriptions of Scott. But the present question is not one that calls for any investigation of Scott, and it is difficult to accept that a question which calls for no investigation of Scott, to which nothing about Scott is relevant, is really about Scott. (p. 209)

On the basis of these considerations, Sprigge makes the following proposal:

I suggest that a property is internal to a particular to the extent that no information about that particular is conveyed by one who says that it might have lacked that property. I think that the distinction between internal and external prop-

erties is not exact.... Let F be any property of a thing a . Then F is an external property of a if something interesting and true may be said of the form “if such and such then not- Fa .” Otherwise F is an internal property. But as from different points of view different things are interesting, so from different points of view different properties are internal and external. (p. 210)

The notion of “internal” is thus not only made a matter of degree but also relativized to the interests and purposes of those who are discussing X . Conceivably, everyone might be interested in X for a widely different reason; in this case, it would be quite possible that everyone might identify X by means of a widely different, but equally true, description. Then there would be no agreement on internal properties, and an Aristotelian metaphysics would seem unintelligible to us. As it stands, however, we tend to be interested in things for roughly the same reasons and thus to group the same things into the same natural kinds (for example, to regard Scott as “essentially” a man, rather than as a collection of physical particles occupying a given stretch of space time, or as a colorful patch on the landscape of nineteenth-century Scotland). Given this agreement and given our natural taxonomical instincts (our tendency to turn differences of degree into differences of kind whenever possible in order to facilitate inquiry), we can explain the commonsensical character of the distinctions between essence and accident and between internal and external properties (and, a fortiori, internal and external relations).

As an account of the internal-external distinction that avoids both the arbitrariness of Aristotelianism and the counterintuitive character of absolute idealism, Sprigge’s proposal is a happy solution. But, like all such solutions, it is no better and no more permanent than the conceptual framework within which it is constructed. There is, to put it mildly, no consensus among philosophers of language as to when a sentence is “about” a given particular, when two sentences are about the same particular, the proper analysis of the notion of “name,” the reducibility of names to descriptions, the assimilation of demonstrative pronouns to proper names, the question of whether proper names can be said to have meanings, the utility of the analytic-synthetic distinction, the equation of “necessary truth” with “analytic truth,” and a host of related issues. In the absence of a comprehensive philosophy of language in which these issues are clarified and resolved in a systematic way, Sprigge’s proposal must be treated as a useful guideline, rather than as a definitive

resolution of the issue concerning internal relations. One can imagine, for example, a revivification of the Aristotelian doctrine of predication, according to which "Socrates is a man" exemplifies a radically different sort of predication from "Socrates is a Greek," such an Aristotelian philosophy of language would, when conjoined with a realistic, anti-instrumentalist philosophy of science, produce a view according to which it would make good sense to say that Socrates's humanity really was internal to him, not simply relative to our interests but absolutely and intrinsically. Such a view would argue that "man" signifies a natural kind and is thus naturally suited to be a predicate "in the category of substance," whereas "Greek" or "atoms located at p at t " is not, and that this is an empirical truth.

There probably would never have been a problem about internal relations were it not for the efforts of speculative metaphysicians, such as Parmenides, Spinoza, and Hegel, to undermine our commonsense conceptual framework. If one rejects such attempts out of hand, one will treat the adoption of monism and of the thesis of the internality of all relations as a *reductio ad absurdum* of the premises from which these views are derived. Since Moore, the vast majority of Anglo-American philosophers have rejected such attempts and have differed only in their diagnoses of the confusions of falsehoods that engendered metaphysical conclusions. As long as the dogma that logical necessity was a matter of linguistic convention remained unchallenged, a simple and elegant resolution of the problem of internal relations seemed possible. However, recent doubts about this dogma (combined with the realization that Aristotle's distinction between essential and accidental properties is not simply a philosopher's invention but is firmly grounded in common sense) have made the problem look more complex than it appeared in the days of Ayer's *Language, Truth and Logic*. Philosophers who wish, as P. F. Strawson has put it, to substitute a "descriptive" metaphysics for a "revisionary" one are now faced with the problem of reconciling (a) the existence of this commonsense distinction with (b) the standard empiricist view that knowledge of how we speak either does not reveal anything about the nature of the objects we refer to, or at least does so in a very different way than does empirical research directed to those objects themselves, (c) the fact that the meaning we assign to a term is in part a function of the amount of empirical knowledge we possess, and (d) the fact that common sense seems to require a realistic, rather than an instrumentalistic, view of what it is to "know the nature of an object."

If the difficulties of such a reconciliation prevent "descriptive" metaphysicians from carrying out their chosen task, then the door will be open once again to the two extreme views examined above. It may turn out that common sense is, if not as incoherent as Parmenides and Bradley thought it, at least sufficiently inconsistent as to require the adoption of paradoxical philosophical theses. Whether one then turns to the extreme represented by Ayer's radical conventionalism and instrumentalism, or to the extreme represented by Blanshard's idealistic monism, will be largely a matter of taste. Both views, as suggested above, are parts of internally consistent philosophical systems. Each system retains certain portions of our commonsense framework and insists on these at the expense of other portions. In the absence of a touchstone other than common sense, it is difficult to see how a rational choice between such systems can be made.

RELATIVITY THEORY

From 1905 to 1915 Albert Einstein revolutionized the conception of space and time and gravity that had been central in physics since Isaac Newton. For a brief discussion of the history of the development of relativity see the entry "Einstein, Albert." This entry describes the content of the theories.

The special and general theories of relativity are, at heart, theories of spatiotemporal structure. They are not particularly about observers or reference frames or ways to synchronize clocks, although as fundamental physical theories they have implications about what observers will observe and what various physical procedures for coordinating clocks will accomplish. It is easy to fall under the impression that these theories are basically concerned about coordinate systems or reference frames because physical events are typically described by means of coordinates or reference frames, but that temptation ought to be avoided.

Perhaps the easiest way to understand special relativity is by analogy to Euclidean geometry. Euclidean geometry postulates a particular spatial structure and, beginning with the Euclid's *Elements*, the implications of that structure for geometrical figures were studied by purely geometrical methods. For two millennia, the study of Euclidean geometry made no use of coordinate systems or of numbers. The introduction of Cartesian coordinates allowed for the translation of geometrical objects into algebraic ones by means of assigning numbers as coordinates to points. There are all sorts of ways to lay down coordinates on a Euclidean space, such as polar coordinates or spherical coordinates, but the most familiar is the system of Cartesian coordinates. Cartesian coordinates are rectilinear and orthogonal; the coordinate curves are straight lines that intersect at right angles. Because of this feature, distances between points in a Euclidean space are easy to calculate from their Cartesian coordinates: If point p has coordinates (x_p, y_p, z_p) and point q has coordinates (x_q, y_q, z_q) , then the distance from p to q is:

$$\sqrt{(x_p - x_q)^2 + (y_p - y_q)^2 + (z_p - z_q)^2}.$$

In most spaces, such as the surface of a sphere, Cartesian coordinates do not exist. It turns out that for a space to be Euclidean is just for the space to admit of Cartesian coordinates. That is, the distances between points in the space must be of just the right form for Cartesian coordinates to exist.

In order to grasp relativity, we have to think not of distances between points in a three-dimensional space, but of a fundamentally spatiotemporal distance between

points in a four-dimensional space-time. Points in the space-time correspond to instantaneous, localized events, such as the bursting of a bubble when it reaches the surface of a glass of champagne. Such events occur both at a place and at a time. To locate these events, we typically ascribe to them four numbers, such as a latitude, longitude, altitude, and time. It is in this uncontroversial sense that the space-time of classical physics and of relativity is four-dimensional.

What sorts of spatiotemporal relations are there between events? All of classical physics agreed on at least one point: There is a definite, objective, purely temporal relation between the events. Two events either take place at the same time, or one takes place a certain amount of time before the other. So the notion of there being a lapse of time between events, and the specific case of simultaneity of events, is inherent in the classical account of space-time structure.

The classical account of spatial structure is not so straightforward. Newton believed that a single three-dimensional Euclidean space persists through time, and that every event, whenever it occurs, takes place somewhere in that absolute space. So Newton thought that any pair of events, no matter whether they occur at the same or different times, have some spatial distance separating them. But consider the following case: On a train traveling along the tracks, there sits a glass of champagne. A bubble rises to the surface and pops, followed a minute later by a second bubble. How far was the first popping from the second?

According to a passenger on the train, the two events took place in close spatial proximity, within a few inches of each other. But according to a spectator watching the train go by, these two events would be considered yards apart because the train has moved in the intervening minute. Newton would insist that there is a true spatial distance between the events, even though no observation could reveal for certain whether the passenger or the spectator (or neither) is right. But a natural reaction is to reject the whole question: There may be definite spatial relations between simultaneous events, but there is no fact at all about the spatial distance between nonsimultaneous events. Thus we arrive at two classical space-time structures: Newtonian space-time, with temporal and spatial relations between every pair of events, and Galilean (or neo-Newtonian) space-time, with temporal relations between all events and spatial relations only between simultaneous events (Galilean space-time then needs to add a new spatiotemporal structure, called an affine connection, to distinguish inertial from non-inertial trajectories). Note that the classical accounts agree on

the temporal structure, and particularly on the objective physical relation of simultaneity.

Special relativity postulates a four-dimensional space-time with a radically different spatiotemporal structure. Instead of having a pure temporal structure and a pure spatial structure, there is a single relativistic “distance” between events (the scare quotes around *distance* must be taken seriously, as the quantity is not at all like a spatial distance). How can this spatiotemporal structure be specified?

The easiest method, albeit a bit roundabout, is by means of coordinates. Here we will take the analogy with Euclidean geometry quite seriously. As we saw, even though Euclidean geometry has no need of coordinate systems, the spatial structure of a Euclidean space can still be specified in this way; a Euclidean space is a space that admits of Cartesian coordinates. More specifically, a three-dimensional Euclidean space has a structure of distance relations among its points such that each point can be given coordinates (x,y,z) and the distance between any pair of points is:

$$\sqrt{(x_p - x_q)^2 + (y_p - y_q)^2 + (z_p - z_q)^2}.$$

In exactly the same way, we can specify the spatiotemporal structure of Minkowski space-time, the space-time of special relativity. Minkowski space-time is a four-dimensional manifold that admits of Lorentz coordinates (or Lorentz frames). A Lorentz frame is a system of coordinates (t, x, y, z) such that the relativistic spatiotemporal distance between any pair of events p and q is:

$$\sqrt{(t_p - t_q)^2 - (x_p - x_q)^2 - (y_p - y_q)^2 - (z_p - z_q)^2}.$$

Written this way, the similarity with the example of Cartesian coordinates on Euclidean space is manifest; the only difference is the minus signs in place of plus signs. The consequences of that small mathematical difference are profound.

Before investigating the nature of this spatiotemporal structure, we should renew some of our caveats. First, there is always the temptation to invest the coordinates with some basic physical significance. For example, it is very natural to regard the coordinate we are calling t as a time coordinate, and to suppose that it has something to do with what is measured by clocks. But as of yet, we have said nothing to justify that interpretation. The Lorentz coordinates are just some way or other of attaching numbers to points such that the quantity defined above is proportional to the spatiotemporal distance between events. Indeed, just as there are many ways to lay down Cartesian coordinates on a Euclidean plane, systems differ with respect to the origin and orientation of the coordinate grid, so there are

many ways to lay down Lorentz coordinates in Minkowski space-time. Different systems will assign different t values to the points, and will disagree about, for example, the difference in t value between two events. We do not invest these differences with any physical significance; because the various systems agree about the quantity defined above, they agree about all that is physically real.

A second caveat is in order. We have been speaking so far as if the spatiotemporal distance between events is itself a number (viz., the number that results when one plugs the coordinates of the events into the formula above). But it is easy to see that this is wrong even in the Euclidean case. Distances are only associated with numbers once one has chosen a scale, such as inches or meters. What exists as a purely geometrical, nonnumerical structure is rather a system of ratios of distances. Having chosen a particular geometrical magnitude as a unit, other magnitudes can be expressed as numbers (viz., the numbers that represent the ratio between the unit and the given magnitude). The Greeks had a deep insight when they divided mathematics into arithmetic (the theory of number) and geometry (the theory of magnitude). They recognized that the theory of ratios applied equally to each field, but kept the two subjects strictly separate. Our use of coordinates to associate curves in space with algebraic functions of numbers has blurred the distinction between magnitudes and numbers. To understand relativity, it is important to recognize the conventions employed to associate geometrical structure with numerical structure.

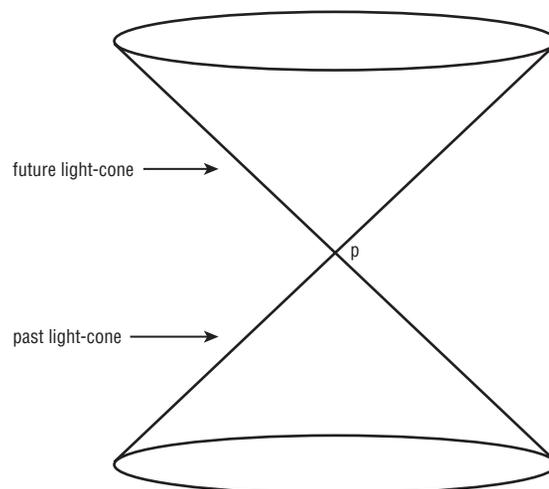

Holding these warnings in mind, let us turn to the relativistic spatiotemporal distance. What are the consequences of replacing the plus signs in the Euclidean distance function with minus signs?

One obvious difference between the Euclidean structure and the Minkowski structure is this: In Euclidean space, the distance between any two distinct points is always positive, and the only zero distance is between a point and itself. In mathematical terms, the Euclidean metrical structure is positive definite. But in the Minkowski structure, two distinct events can have zero distance between them. For example, the events with coordinates $(0,0,0,0)$ and $(1,1,0,0)$ have zero distance (where we list the coordinates in the order (t,x,y,z)). Of course, this does not mean that these two events are the same event; assigning the numerical value zero to this sort of distance is just a product of the conventions we have used for assigning numbers to the distances. But the fact that two events have a zero distance between them does show that they are related in a particular spatiotemporal way. In order to remind ourselves that these spa-

tiotemporal distances do not behave like spatial distances, from now on we will call them spatiotemporal intervals.

If we choose a particular event, the popping of a particular champagne bubble, and call the event p , then we can consider the entire locus of events that have zero interval from p . There will be infinitely many such events. If p happens to be at the origin of a Lorentz frame, assigned coordinates $(0,0,0,0)$, then among the events at zero interval from it are $(1,1,0,0)$, $(1,0,1,0)$, $(5,0,-3,4)$, and $(-6,4,-4,2)$. To get a sense of how these events are distributed in space-time, we draw a space-time diagram, but again one must be very cautious when interpreting these diagrams. The diagrams must represent one or two dimensions of the space-time, because we cannot draw four-dimensional pictures, but that is not the principle problem. The main problem is that the diagrams are drawn on a Euclidean sheet of paper, even though they represent events in Minkowski space-time. There is always the danger of investing some of the Euclidean structure of the representation with physical significance it does not have. Bearing that in mind, the natural thing to do is to suppress the z coordinate and draw the x , y , and t coordinates as the x , y , and z coordinates of three-dimensional Euclidean space.

Adopting these conventions, the points at zero interval from $(0,0,0)$ will be points that solve the equation $t^2 - x^2 - y^2 = 0$, or $t^2 = x^2 + y^2$. The points that solve this equation form a double cone whose apex is at the origin. According to relativity, the intrinsic spatiotemporal structure associates such a double cone with every event in the space-time. This locus of points is called the light-cone of the event p , and divides into two pieces, the two cones that meet at p . These cones are called the future light-cone and the past light cone of p .

As the name light-cone suggests, we are now in a position to make contact between the spatiotemporal structure postulated by relativity and the behavior of physical entities. According to the laws of relativistic physics, any light emitted at an event (in a vacuum) will propagate along the future light-cone of the event, and any light that arrives at an event (in a vacuum) arrives along the past light-cone. So the tiny flash of light emitted when our champagne bubble pops races away from the popping event along its future light-cone. One can think of the ever-growing light-cone as representing the expanding circle (or, if we add back the z dimension, the expanding sphere) of light that originates at the bursting of the bubble.

Having associated the spatiotemporal structure with the behavior of an observable phenomenon such as light, we can now see how relativistic physics gains empirical content. For example, it is an observable fact that any pair of light rays traveling in parallel directions in a vacuum travel at the same speed; one light ray in a vacuum never overtakes another. This is not, of course, how material particles behave. One spaceship traveling in a vacuum can overtake another, or one electron in a vacuum can overtake another, because where a spaceship or an electron goes depends on more than the space-time location of the origin and direction of its journey. Two electrons can start out at the same place and time and set off in the same direction but end up in different locations because they were shot out at different speeds. Their trajectories depend on more than just the space-time structure. Light, in contrast, is intimately and directly tied to the relativistic space-time structure. Space-time itself, as it were, tells light in a vacuum where to go.

The assignment of zero relativistic interval between the origin of a light-cone and any event on it has one other notable consequence. We have already said that when we assign numbers to magnitudes, we want the ratios between the numbers to be identical to the ratios between the magnitudes. Because $0:0$ is not a proper ratio, the relativistic interval does not license comparisons between the various intervals on a light-cone. If one light ray originates at $(0,0,0,0)$ and travels to $(1,1,0,0)$, and a second light ray originates at $(0,0,0,0)$ traveling in some other direction, there is no fact about when the second light ray has gone as far as the first.

What other structure, beside the light-cone structure, does Minkowski space-time have? There is a well-defined notion of a straight line in the space-time, and this is accurately represented in our Euclidean space-time diagram: Straight lines in the Euclidean diagram corre-

spond to straight trajectories in the space-time. Indeed, we have tacitly been appealing to the notion of a straight line all along; when we speak of the relativistic interval between two events, we mean the interval as measured along a straight line connecting the events, or, even more precisely, we mean the relativistic length of the straight line that connects the events. The straight-line structure (affine structure) of Minkowski space-time plays a central role in framing physical laws.

If a light ray is emitted from $(0,0,0,0)$ into a vacuum, we already know that its trajectory through space-time will lie on the future light-cone of $(0,0,0,0)$. But more than that, the trajectory will be a straight line on the light-cone. An analogous fact holds for material particles that travel below the speed of light. If a material particle is emitted from $(0,0,0,0)$, its trajectory will lie entirely within the future light-cone of $(0,0,0,0)$, which is to say that the particle can never travel at or above the speed of light. But more than that: If the particle is emitted into a vacuum, and is not subject to any forces, then its trajectory will be a straight line in space-time.

This law, in abstract form, enormously predates the theory of relativity. For this is just the proper space-time formulation of Newton's first law of motion: "Every body continues in its state of rest, or of uniform motion in a right line, unless compelled to change that state by forces impressed on it." The trajectory of a particle at rest or in uniform motion in Newtonian space-time is a straight line through the four-dimensional space-time. Newton's first law, stated in terms of space-time trajectories, also retains the same form in Galilean space-time, and can be taken over without change into Minkowski space-time. As we will see, in this abstract space-time formulation, Newton's first law also holds in the general theory of relativity. That is why we should try to formulate physical laws directly in terms of space-time structure.

Once we deal with material particles that travel below the speed of light, the relativistic interval takes on even greater significance. Consider a particle that travels from $(0,0,0,0)$ to $(5,4,0,0)$ along a straight trajectory (i.e., a particle emitted from the origin of the coordinate system that arrives at the event $[5,4,0,0]$ without having any forces acting on it). The relativistic interval along its space-time trajectory is:

$$\sqrt{(5-0)^2 - (4-0)^2 - (0-0)^2 - (0-0)^2} = 3.$$

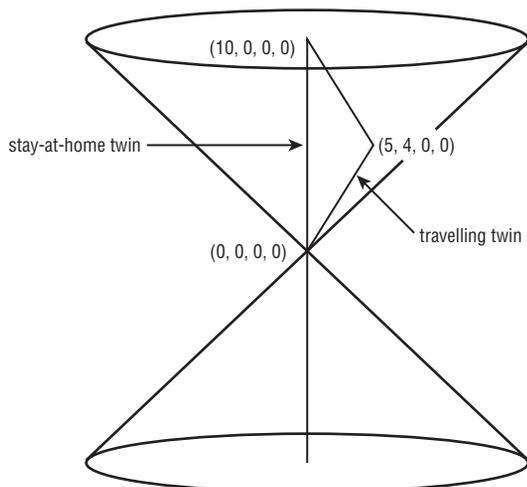

The size of this interval has direct physical significance; it is proportional to the amount of time that will elapse for a clock that travels along that trajectory. Clocks in the theory of relativity are like odometers on cars; they meas-

ure the length of the path they take. But *length* here means the interval, and *path* the space-time trajectory of the clock. Events in space-time separated by positive intervals are time-like separated.

It is not, of course, a further unanalyzable postulate of relativity that clocks measure the interval along their trajectory; clocks are physical mechanisms subject to physical analysis. But one can easily analyze how a simple clock will behave, such as a clock that counts the number of times a light ray gets reflected between two mirrors, and find that the reading on the clock will be proportional to the interval along the clock's trajectory.

With the clock postulate in hand, we can now analyze the notorious *twins paradox* of relativity. One of a pair of twins takes a rocket from Earth and travels to a nearby star. Upon returning to Earth, the twin has aged less than the stay-at-home sister, and the clocks in the twins' spaceship show less elapsed time than those that remained on Earth. Why is that?

To be concrete, suppose the event of the rocket leaving Earth is at the point $(0,0,0,0)$ in our coordinate system, and the rocket travels inertially (without acceleration) to the point $(5,4,0,0)$. The rocket immediately turns around, and follows an inertial trajectory back to Earth, arriving at the event $(10,0,0,0)$. The interval between $(0,0,0,0)$ and $(5,4,0,0)$ is, as we have seen, 3. Suppose this corresponds to an elapse of three years according to the onboard clocks. The return trajectory from $(5,4,0,0)$ to $(10,0,0,0)$ also has an interval length 3, corresponding to another three years elapsed. So the astronaut twin arrives back having aged six years, and having had all the experiences that correspond to six years of life.

The stay-at-home twin, however, always remained at the spatial origin of the coordinate system. Her trajectory

through space-time is a straight line from $(0,0,0,0)$ to $(10,0,0,0)$. So the interval along her trajectory is 10, corresponding to an elapse of ten years. She will have biologically aged ten years at her sister's return, and had four more years of experience than her twin.

The relativistic analysis of the situation is quite straightforward. It is really no more surprising, from a relativistic perspective, that the clocks of the twins will show different elapsed times from departure to return than it is surprising that two cars starting in the same city and end in the same city will show different elapsed mileage on their odometers, given that one took the free-way and the other a winding scenic route. The sense that there is a fundamental puzzle in the twins paradox only arises if one has mistaken views concerning the content of the theory of relativity.

In particular, it is often said that, according to the theory of relativity, all motion is the relative motion of bodies. If so, then there seems to be a complete symmetry between the twins: The motion of twin A relative to twin B is identical to the motion of twin B relative to twin A. But the relative motion of the twins plays no role at all in the physical analysis of the situation. The amount of time that elapses for twin B on her trip has nothing to do with what twin A is doing, or even if there is a twin A. The amount of time is just a function of the space-time interval along her trajectory.

It is also sometimes said that the theory of relativity gets rid of all absolute spatiotemporal structure; all facts about space and time are ultimately understood in terms of relations between bodies, so in a world with only one body there could be no spatiotemporal facts. This is also incorrect. The special theory of relativity postulates the existence of Minkowski space-time, whose intrinsic spatiotemporal structure is perfectly absolute, in whatever sense one takes that term. It is not a classical space-time structure, but it is not just a system of relations between bodies.

One occasionally also hears that the resolution of the twins paradox rests on facts about acceleration; the situation of the two twins is not exactly symmetric because the astronaut twin must accelerate (when she turns around to come home), whereas the stay-at-home twin does not. That is true, but irrelevant: The difference in elapsed time is a function of the intervals along the trajectories, not a function of the accelerations that the twins experience. Indeed, in the general theory of relativity we will be able to construct a twins scenario in which neither twin accelerates at all, but still they suffer different elapsed times between parting and reunion. It would be just as mis-

leading to attribute the difference in elapsed time to the accelerations of the twins as it would the difference in odometer reading to the accelerations of the cars, even if the car that took the longer route did accelerate more.

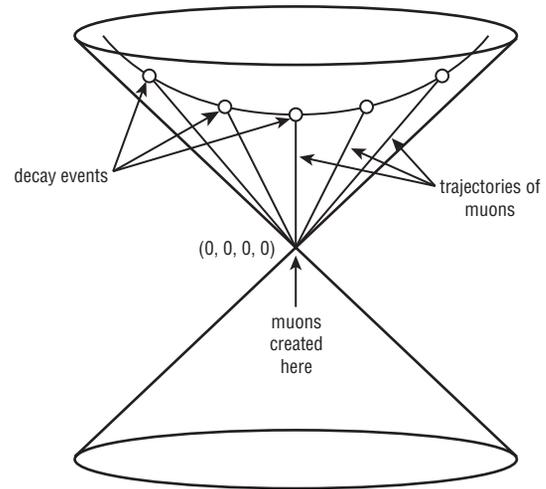

The paradoxical or puzzling aspect of the twins paradox really arises from the difference between Euclidean geometry and Minkowski space-time geometry. If we draw the trajectories of the twins in space-time, we get a triangle whose corners lie at $(0,0,0,0)$, $(5,4,0,0)$, and $(10,0,0,0)$. The astronaut twin travels along two edges of this triangle, whereas the stay-at-home twin travels along the third. And in Euclidean geometry, the sum of the lengths of any two sides of a triangle are greater than the length of the remaining side. But in Minkowskian geometry, the opposite is true: The sum of the intervals of two sides is less than the interval along the remaining side. Indeed, for time-like separated events, a straight line is the longest path between the two points in space-time. This is one consequence of exchanging the plus signs in the Euclidean metric for minus signs in the Minkowski metric.

The relativistic clock postulate has been most strikingly checked using natural clocks: unstable particles whose decay rate displays a known half-life in the laboratory. The muon, a sort of heavy electron, is unstable and will decay on an average of 10^{-6} seconds after having been created. Muons can be created in the upper atmosphere by collisions between molecules in the air and high-energy cosmic rays. According to clocks on Earth, it should take the muon about 10×10^{-6} seconds to reach the Earth, so very few should survive the trip without decaying. Nonetheless, many more muons than that calculation suggests do reach the Earth's surface. Calculation of the interval along the muon's trajectory predicts this because that interval corresponds to less than 10^{-6} seconds.

If we idealize muons a bit, and imagine that they all decay in exactly 10^{-6} seconds (according to their own clocks), then we can use them to map out the geometry of Minkowski space-time. Suppose we create a swarm of muons in space and send them out in all directions. Their decays will provide a map in space-time of events that are all the same interval from the point of creation. If we choose units so that the size of the interval corresponds to seconds, and we choose the creation of the muons as the origin of the coordinate system, then the coordinates of the decay events will satisfy:

$$\sqrt{t^2 - x^2 - y^2 - z^2} = 10^{-6}$$

This is the equation of a hyperboloid of revolution that asymptotically approaches the light-cone, as depicted below.

The hyperboloid represents events all at the same interval from $(0,0,0,0)$, and so corresponds to a circle or sphere of fixed radius in Euclidean geometry. There would be a corresponding hyperboloid in the past light-cone, representing places from which a muon could have been sent that would have decayed at $(0,0,0,0)$.

Indeed, we are now in a position to make a thoroughgoing analogy between the geometry of Minkowski space-time and Euclidean geometry that makes no reference to coordinates at all. Classical Euclidean geometrical proofs do not use coordinate systems of numbers, they use two instruments: the straightedge and the compass. The straightedge allows one to identify straight lines in the space, and the compass to draw the locus of points at a fixed distance from a given center. In Minkowski space-time, we can use light rays in a vacuum and inertially traveling particles as straightedges because their trajectories are straight lines in the space-time. Setting a Minkowski compass at interval zero and identifying a center should result in drawing the light-cone: the locus of points of interval zero from the center. So we can use light rays for this purpose. Setting the compass to draw points at a fixed positive interval should result in drawing hyperbola; we can use clocks for this just as the muons are employed above. In this way, we can free Minkowski geometry from coordinates altogether.

So far we have left one species of space-time relation out of account. All the points on the past or future light-cone of some event p are at zero interval from p . All the events inside the past or future light-cone are at positive interval from p (taking always the positive square root by

convention). What of points that are outside the light-cone altogether?

The point labeled (0,1,0,0) is outside the light-cone of the point (0,0,0,0). If we plug these coordinates into our formula, we find that the interval between the points is:

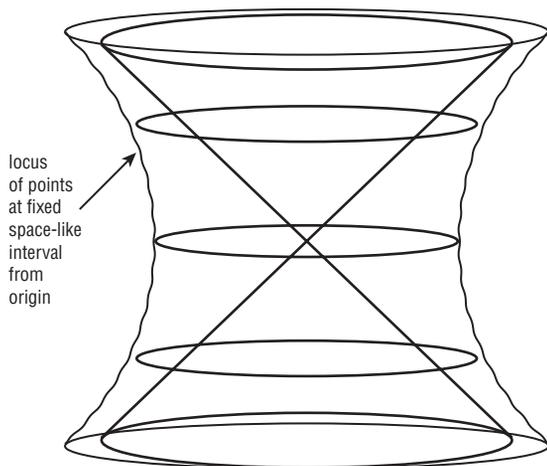

$$\sqrt{(0-0)^2 - (1-0)^2 - (0-0)^2 - (0-0)^2} = \sqrt{-1} = i.$$

That is, according to the definition of the interval that we have given, the interval between these points is imaginary. What could this mean?

Once again, we have to recall that the assignment of numbers to the intervals is somewhat a matter of convention. In fact, some physics books define the interval as:

$$\sqrt{(x_p - x_q)^2 + (y_p - y_q)^2 + (z_p - z_q)^2 + (t_p - t_q)^2},$$

Here the interval between time-like separated events becomes imaginary. Does this mean that a clock could measure an imaginary number? Of course it can: Just take a regular clock and paint a little *i* after all the numerals! The numbers we assign to intervals have no intrinsic significance; it is the ratios between the numbers that represent the ratios among the magnitudes. Events that lie outside each other's light cones, so-called space-like separated events, have intervals among them that also stand in ratios to each other. The set of events at fixed space-like separation from (0,0,0,0) forms another sort of hyperboloid of revolution, depicted below.

We now have a sense of the spatiotemporal structure of Minkowski space-time. A special relativistic physical theory must have laws that employ only this spatiotemporal structure. We could now go on to see how, for example, classical electromagnetic theory can be reformulated in this way, but that would take us too far from foundational issues.

It should be noticed that this account of special relativity has made no mention at all of several well-known features often associated with relativity, such as the constancy of the speed of light, the relativity of simultaneity, and the Lorentz-Fitzgerald contraction. That is because all of these are frame-dependent (or coordinate system dependent) effects, and we have been presenting the theory in a frame-independent way. For example, we have no basis to discuss the relativity of simultaneity because we have had no ground, and no need, to introduce any notion of simultaneity at all. In classical physics, simultaneous events are events that take place at the same time, but we have no general notion of the time at which an event occurs, only the time that elapses on a clock following a certain trajectory. So the proper thing to say is not that special relativity implies the relativity of simultaneity, but that it implies the nonexistence of any objective notion of simultaneity. And we cannot discuss whether the speed of light is constant because we do not have any grounds to ascribe any speed to anything.

We have seen that a light ray can never overtake another light ray, but assessing a speed requires determining how far an object went in a given period of time. So far, we have not needed any notion of the distance an object travels, nor of the time that it takes to travel that distance. We can say how much time will elapse on a clock that follows a given trajectory, but that is evidently no use in defining a speed of light; no material clock can travel along with a light ray, and if it could, it would show no elapsed time for the journey. The notion of simultaneity requires a global time function, that is, an assignment of times to all events, so that there is a locus of events that are all assigned the same time. And the notion of a speed requires both the notion of the time that elapses between the start and the end of a journey, and the notion of the distance covered in that time. The relativistic space-time structure does not, per se, support either of these notions.

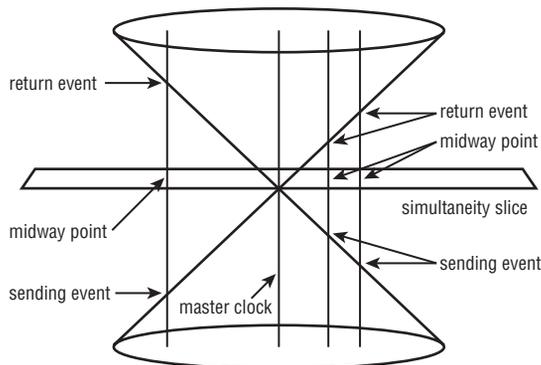

There is, however, a reasonably natural method for introducing both a global time function and a notion of spatial distance into Minkowski space-time. We begin with a family of co-moving inertial clocks (i.e., a family of clocks all moving on straight, parallel trajectories through space-time). There will be an infinitude of such families, corresponding to all the directions their trajectories can have. We begin by picking one such family.

We now want to “synchronize” the clocks. Scare quotes have to be put around the word since the classical notion of synchronization presupposes the notion of simultaneity: Synchronized clocks all show the same time at the same instant. But in relativity there is no such thing

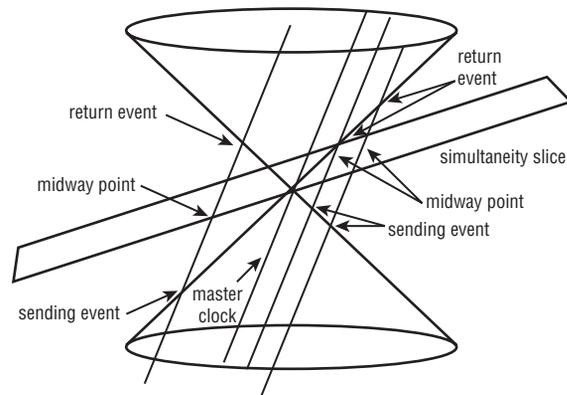

as *the same instant*. So one must think of the method we are about to describe as a way to coordinate a family of clocks that we simply call synchronizing them.

Let us choose a single master clock from our family of co-moving clocks. The other clocks will coordinate with this master clock by the following method: Each clock sends a light ray to the master clock, noting the time of emission (according to the sending clock). When the light ray reaches the master clock, it is immediately sent back and shows the time reading on the master clock at the moment it arrived. When this return signal reaches the sending clock, the time reading on the sending clock is noted. The sender, then, has three bits of data: the time it sent the signal (according to the sending clock), the time it received the return signal (ditto), and the reading on the master clock when the signal got to it. On this basis, the sending clock synchronizes with the master clock by adjusting its time so that the time that the master clock read when the signal arrived corresponds to the event on the sending clock exactly midway between the moment the signal was sent and the moment the return signal arrived. All of these notions are relativistically well-defined, so this method of coordinating clocks can be carried out. Every event in space-time is now assigned a time (viz., the reading on that member of the family of clocks that passes through the event when it passes through the event).

We can now identify simultaneity according to this family of clocks as sets of events that are all assigned the same time by this family of clocks. Such a set is called a simultaneity slice through the space-time. The figure below shows one such simultaneity slice. Because all of the light signals that reach the master clock at noon lie on the past light-cone of the master clock showing noon, and because all of the return signals lie on the future light-cone of that event, it is easy to calculate the points at which all of the coordinated clocks will register noon. It is the flat plane in the middle.

The simultaneity slice is a function of which family of co-moving clocks we choose. Choosing another family will give a different notion of simultaneity:

Each family of co-moving clocks determines its own notion of simultaneity, and these various notions render different judgments concerning which pairs of events happen at the same time. All the families will agree about the time order of time-like or light-like separated events, but for any pair of space-like separated events, some families will say that they happened at the same time, others that one happened first, and yet others that the other happened first. Each family introduces its own global time function. None of these functions is superior to the other, and none is needed at all to explicate the basic spatio-temporal structure.

What of spatial distance? Once a family of clocks has been synchronized, there is a simple way to assign a spatial distance between any pair of clocks. Send a light ray from one clock to the other. We can now understand the time of travel for the light ray as the difference between the time showing on the emitting clock at the emission event and the time showing on the receiving clock at the reception event. So we now have a definition of how long the light ray took to get from one clock to the other (again, this is not the time that a clock traveling along with the light ray would show elapsing). If we now define the speed of light to be a given constant, c , then we can say that the distance between the clocks is just c times the elapsed time of transmission. This will give us a structure of spatial distances between the clocks as defined by that particular family of clocks. Those spatial distances will, in special relativity, constitute a Euclidean space. Different families of clocks will disagree about the precise spatial distance between events, and about the spatial size of material objects, but each family will construct for itself a Euclidean spatial structure. Finally, if we allow such a

family of clocks to introduce Cartesian coordinates on its Euclidean space, then the family will assign each event four coordinate numbers: the three spatial coordinates and the global time function. These are exactly the Lorentz coordinate frames that we began with to express the relativistic metric, so we have come full circle.

The interconnection between the global time defined by a family of clocks and the spatial structure among events defined by that family resolves many of the intuitive puzzles in special relativity. We have seen that, according to clocks at rest on the Earth, a high-energy muon has a much longer lifetime than a muon at rest. That explains, from the point of view of the Earth frame, how the muon manages to make the trip to the surface. But of course, from the point of view of the muon, and clocks co-moving with it, the muon lifetime is the normal 10⁻⁶ seconds. From their point of view, the Earth is approaching them at high velocity. In that frame of reference, the muon is able to get through the whole atmosphere not because of any slowing down of their clocks, but because of the spatial contraction of the atmosphere. In the muon's frame of reference, the distance from the upper atmosphere to the Earth is much less than we on Earth take it to be.

The Lorentz contraction and time dilation effects of relativity then arise as disagreements that occur between the Lorentz frames about the amount of time that elapses between events and the spatial distance between events. Clocks in any frame will be seen to run slow according to the time function associated with any other frame. A meter stick at rest in one frame will be judged to be less than a meter long according to a frame in which the stick is moving. These are symmetric effects: From the point of view of any Lorentz frame, clocks at rest in any other frame run slow. We need to sharply distinguish these effects from the twins paradox. There, the difference in elapsed time for each twin is a consequence of the fundamental spatiotemporal structure, and has nothing to do with frames or families of clocks. The time dilation between frames results only from different ways of defining coordinates. In the latter case, there is no fact about which set of clocks is really running slower, but in the former case there is an objective fact about which twin is biologically younger when they are reunited.

GENERAL RELATIVITY

Special relativity is a theory that postulates a certain intrinsic spatiotemporal structure, and then formulates the laws of physics in terms of that structure. General relativity is the relativistic theory of gravity. It is also funda-

mentally a theory about spatiotemporal structure, and allows for different structures than special relativity. So the first question that arises when approaching general relativity is why gravity should particularly be connected to spatiotemporal structure. The special relativistic theory of electromagnetism, for example, simply accepts the Minkowski space-time and employs it in framing the electromagnetic laws. But gravity, in contrast, led to the rejection of special relativity in favor of a new theory. What is so special about gravity?

One sometimes hears that there needed to be a relativistic theory of gravity because Newton's gravitational theory postulates that gravity acts instantaneously between distant masses, but in relativity there is no available notion of instantaneous action (because there is no physical notion of simultaneity). But this observation does nothing to suggest that the theory of gravity should require any change from the special relativistic space-time. Classical electrostatics postulated that the coulomb force between distant charged particles acts instantaneously, but electromagnetic phenomena do not require changes to special relativity. Rather, relativistic electrodynamics simply rejects the claim that electric and magnetic forces act instantaneously. Electromagnetic influences are propagated along the light cones, at the speed of light, by electromagnetic waves. Similarly, one might think that the obvious way to deal with gravitation is simply to deny that it acts instantaneously. Let the gravitational effects also propagate along the light cones, and the special relativistic structure can be used to formulate the laws.

Adding such a delay in gravitational influence would, of course, modify the predictions of Newtonian gravity. One might even plausibly argue that Newton himself would have expected such a correction to his instantaneous gravity. For Newton thought that gravitational forces were mediated by particles exchanged between the gravitating bodies, and he would have expected the particles to take some time in traveling between the bodies. Of course, the fundamental cause of the gravitational force was a topic on which Newton refused to *fingere* any hypothesis, so we must be a bit speculative here. But it is worthwhile to note that if we modify classical Newtonian gravitational theory to allow gravitational influence to propagate along the light cones, we can exactly derive some famous relativistic effects, such as the anomalous advance in the perihelion of Mercury.

In order to understand why gravity is plausibly taken to be deeply connected to space-time structure, we need to look elsewhere. Consider again the family of co-moving inertial clocks we made use of in our discussion

of special relativity. Once set in motion, the family of clocks will move together, never approaching or receding from each other. That is because: a) the clocks are all traveling inertially, not subject to any force; b) according to the space-time version of Newton's first law, the trajectories of bodies subject to no forces will be straight lines in space-time; and c) the straight-line trajectories of the co-moving clocks form a family of parallel straight lines. Note that in giving this argument, we never had to mention the mass of any of the clocks. Because they are moving inertially, the trajectories of the clocks are determined by the intrinsic space-time structure, without the mass playing any role. It would not matter if some of the clocks were heavy and others light; they would still move together parallel to one another.

In Newtonian physics, the mass of a body only comes into consideration when a body is subject to a force and thereby deflected off its inertial trajectory. The inertial mass of a body is nothing but a measure of the body's resistance to being deflected by a force from its inertial trajectory: The more massive a body is, the harder it is to make its trajectory bend in space-time. Newton's second law, which we now render $F = mA$, tells us that the same force will only produce half the acceleration in a body that is twice as massive. So in the presence of forces, the trajectories of bodies will depend on their masses, whereas in the absence of forces the more and less massive bodies will move on parallel trajectories. Turning this observation around, we should find it very suggestive if there is a situation in which the trajectory of a body does not depend at all on its mass. It is natural to suspect that in such a situation, the mass of the body is playing no role because the body is not being subject to any force; it is moving inertially.

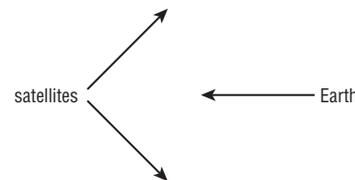

Recall Galileo at the top of the Leaning Tower of Pisa dropping a lighter and heavier object and seeing them hit the ground together. Here is a common situation in which the mass of an object does not affect its trajectory: The heavy and light follow the same space-time path. According to Newtonian gravitational theory, this is a rather fortuitous result. In that theory, both the heavy and the light object are subject to a force, the force of gravity, and so each is being deflected off its inertial trajectory. But, luckily, the gravitational force on each object is exactly proportional to its inertial mass. So the more massive object, which needs a greater force to be accelerated, is subject to a greater force than the less massive object. Indeed, the gravitational force on the more massive object is exactly as much larger as it needs to be to produce precisely the same acceleration as the lesser force

of gravity produces on the less massive object. That, according to Newton, is why they fall together; they are both accelerated, but at exactly the same rate.

If we follow the hint above, though, we will be led to suspect a different account. Perhaps the two objects move together not because they are equally deflected off their inertial, straight-line trajectories, but rather because they are both following their inertial trajectories. Because the inertial trajectories are straight lines in space-time, this suggests a deep connection between gravity and fundamental spatiotemporal structure.

In this way we arrive at the general theory of relativity. According to general relativity, objects that are falling in a gravitational field or under the influence of a gravitational force are not being affected by any force at all. Gravity does not deflect objects from their inertial paths, it rather influences the very structure of space-time itself. The balls falling from the Leaning Tower of Pisa, or the planets orbiting the sun, are following straight trajectories through space-time.

To realize this theory, we must reject Minkowski space-time. Consider, for example, two satellites orbiting the Earth in opposite senses. The space-time diagram of the situation looks like this:

As the satellites orbit, their paths cross and recross in space-time. But in Minkowski space-time, as in Euclidean space, two straight lines can intersect only once at most. So the space-times of general relativity must have a different spatiotemporal structure than the space-time of special relativity.

An analogy with pure spatial geometry helps here. Euclidean geometry is just one of an infinitude of spatial geometries. Lines on the surface of a sphere, for example, do not satisfy Euclid's postulates. But even spherical geometry is highly regular compared to most geometries. Consider, for example, the surface of North America. In regions of the Great Plains, the geometry is nearly Euclidean (and even more nearly spherical), whereas in the Rocky Mountains the geometry of the surface varies wildly from place to place. We need new mathematical machinery to deal with this sort of situation.

The general mathematics needed is called differential geometry. Differential geometry is suited to deal with spaces whose geometrical structure varies from place to place. In some regions, a space may be locally Euclidean, in others non-Euclidean, so we have to be able describe the geometry region by region.

Euclidean spaces have a particularly uniform geometrical structure that allows them to admit of very convenient coordinate systems. As we have seen, a Euclidean space admits of Cartesian coordinates, in which the distances between points is a simple mathematical function of the coordinates of the points. Non-Euclidean spaces do not admit of such convenient systems. For example, points on a sphere can be coordinatized by latitude and longitude, but distances between the points on a sphere are not a simple function of their coordinate differences. If you are near the North Pole, you can change your longitude by several degrees just by taking a few steps; near the equator the same change of longitude would require traveling hundreds of miles. And even spherical coordinates are relatively simple and uniform.

To get a sense of a completely generic coordinate system, imagine walking down a road where each successive house has an address—one greater than the house before. You want to get to house number 200 and you are currently at house 100. How far must you walk?

There is no way to tell. If you go through a densely populated area, such as a small town, you will get to your destination quickly. If it is a sparsely built region, you may have to walk a long way. To know how far you have to go, you would need a complete listing of the distances between successive houses. If you have such a list, you can calculate the distance between any two houses, and so can reconstruct the geometrical structure of the region where the houses are built. In an analogous way, the general theory of spaces allows for the use of any arbitrary coordinate system. Accompanying the system is a metric that specifies the distances between nearby points. We do not have any general rule for calculating distances between distant points as a function of their coordinates, but we do not need one. The distance between faraway points is just the length of the straight path that connects them, and we can calculate the length of that path by knowing the distance between nearby points and adding up all the distances along the path. Thus we have the mathematical tools to deal with generic spaces of variable curvature that admit of nothing like Cartesian coordinates.

It is sometimes said that the general theory of relativity requires us to replace Euclidean space with a non-Euclidean space, but that is not a very useful, or accurate,

explanation of the situation. As we have seen, even in special relativity the notion of spatial geometry is rather derivative and non-fundamental. The fundamental notion is the relativistic interval, which is a spatiotemporal object. It is only relative to a family of co-moving objects, such as clocks, that we can even define a spatial geometry. It turns out that, in special relativity, each such family will ascribe Euclidean geometry to its space, but that is somewhat fortuitous; there is no logical guarantee that the various families will agree on their findings. After all, in special relativity the various families will disagree about the exact spatial distance (and temporal gap) between a given pair of events. In general relativity, there will, in general, not exist families of co-moving inertial observers that maintain the same spatiotemporal relations to one another, and so there is no unproblematic way to define a spatial geometry at all.

In any case, it is simply incorrect to say that objects moving in a gravitational field trace out straight paths in a non-Euclidean spatial geometry. The orbits of the planets, for example, are nearly elliptical in any reasonably defined space for the solar system, and the ellipses are not (spatially) straight lines.

The proper account of general relativity rather employs an analogy. As the variably curved non-Euclidean spaces are to Euclidean space, so the variably curved space-times of general relativity are to Minkowski space-time. The orbits of the satellites depicted above are not straight paths in any spatial geometry, but they are straight paths in space-time. The effect of the Earth is not to produce a force that deflects the satellites off their inertial paths, it is to alter the space-time geometry so that it contains inertial paths that cross and recross.

On the Newtonian picture of gravity, when we sit on a chair we are not accelerated because we are acted on by counterbalancing forces: The gravitational force pulling us down and the force of the chair pushing us up. According to the general relativistic account, the force of the chair pushing us up still exists, but it is unbalanced by any gravitational force. It follows that according to general relativity, as we sit we are constantly accelerated (i.e., constantly being deflected off of our inertial, straight-line trajectories through space-time). The inertial trajectory is that of an object unsupported by anything like the chair (i.e., an object in free fall).

The curvature of general relativistic space-time is partially a function of the distribution of matter and energy; that is why space-time near a massive object like the Earth is curved in such a way as to produce a gravitational field. This connection between the matter and

energy distribution and the spatiotemporal geometry is provided by Einstein's general relativistic field equations. But although the distribution of matter and energy influences the space-time geometry, it does not completely determine it.

The situation is similar to the relationship between the electromagnetic field and the electric charge distribution in classical physics. The presence of electric charges contributes to the electromagnetic field, but does not, by itself, determine it. For example, even in a space devoid of electric charges, there can be a nonzero electromagnetic field: electromagnetic waves (i.e., light) can propagate through the vacuum. Similarly, the general theory predicts the existence of gravitational waves—disturbances of the spatiotemporal geometry that can exist even in the absence of any matter or energy and that propagate at the speed of light. There are, for example, many vacuum solutions of the Einstein field equations. One solution is Minkowski space-time, but other solutions contain gravitational waves.

Because general relativity concerns spatiotemporal structure, and because the trajectory of light rays is determined by the light-cone structure, general relativity must predict the gravitational bending of light. It is not clear whether Newtonian physics would predict any gravitational effect on light because that would depend on whether light feels any gravitational force, but light certainly does propagate through space-time. The effect of gravity on light was dramatically confirmed in Arthur S. Eddington's 1919 eclipse expedition, but is even more strikingly illustrated in the phenomenon of gravitational lensing: A galaxy positioned between the Earth and a more distant light source can act as a lens, focusing the light of the distant source on the Earth. Two astronauts traveling inertially could experience a similar effect; they could take different straight paths that both originate at their home planet and both end on Earth, going different ways around an intervening galaxy. Because the relativistic interval along those paths could differ, such astronauts could illustrate the twins paradox without any acceleration; twins coming from the distant planet could have different biological ages when they reunite on Earth, even though neither suffered any acceleration.

The spatiotemporal geometry of general relativity accounts for familiar gravitational phenomena, but the theory also has dramatic consequence at the cosmological scale and in extreme physical conditions. When a massive star burns through its nuclear fuel and collapses, for example, the increasing density of matter causes ever greater curvature in space-time. If the star is sufficiently

massive, the light-cone structure deviates enough from Minkowski space-time to form a trapped surface: a region from which light cannot escape. The event horizon around a black hole is such a trapped surface; an object falling through the horizon can never send light, or any other signal, back to the exterior region. Once the infalling matter of the star reaches this point, it is destined to become ever more compressed without limit, and the curvature of the space-time will grow to infinity. If the equations continue to hold, this results in a space-time singularity; the spatiotemporal structure cannot be continued beyond a certain limit and space-time itself comes to an end. Because the spatiotemporal structure itself has become singular, it no longer makes any conceptual sense to ask what happens after the singularity; no meaning could be attached to the term after in the absence of spatiotemporal structure.

In the opposite temporal direction, the general theory also contains models in which the universe as a whole arises out of such a singularity, the singularity we call the big bang. Indeed, if general relativity is not modified, the observed motions of galaxies require that the universe began at a singularity, and that space-time itself has been expanding ever since. There is equally no sense to be made of the question what happened before the big bang because the spatiotemporal structure needed to define temporal priority would not extend beyond the initial singularity.

It is, of course, possible that the equations of the theory will be modified in some way so as to avoid the infinities and singularities, but that takes us from the analysis of general relativity into speculations about the replacement of general relativity. The mathematical structure of general relativity also admits of models of the theory with very peculiar spatiotemporal structures. Some models, for example, admit closed time-like curves, that is, time-like trajectories that loop back through space-time and meet up with themselves. In such a model, a person could in principle continue going always locally forward in time, but end up (as an adult) back at the events of their childhood. There seems to be no way to physically test this possibility (that is, there is no physical mechanism to produce closed time-like curves through laboratory operations), so it is unclear whether the existence of these mathematical models proves the physical possibility of such time travel or rather the physical impossibility of space-times that correspond to these mathematical solutions. In any case, general relativity provides a means for considering spatiotemporal structures unlike any that occur in classical physics.

The special and general theories of relativity provide a rich source of novel concepts of great interest to metaphysics. The topics that could be informed by these theories are too long even to list, but the most obvious metaphysical implications of the theories are worthy of remark. The nature of space and time occupies a central place in Immanuel Kant's *Critique of Pure Reason*, where supposed a priori knowledge of spatial and temporal structure provided grounds for the conclusion that space and time have no existence outside the faculty of intuition. After all, how could one know anything a priori about space and time if they exist outside the mind?

The theories of relativity simply refute the claim that there is any a priori knowledge of spatiotemporal structure. Even if relativity ultimately proves to be incorrect, everything in our everyday experience of the world can be accommodated in the relativistic spatiotemporal account. For all we know at present, we could be living in a relativistic universe, in which there is no Euclidean space and in which even time need not have a universal linear order. The nature of space and time is a matter of empirical inquiry, not a priori proof.

The special and general theories are also relevant to the question of the nature of space and time: Are they entities in their own right (as Newton supposed) or just relations among material bodies (as G.W. Leibniz insisted)? Taken at face value, the theories posit an independent existence to the four-dimensional space-time manifold. Even in the absence of material bodies, there is a spatiotemporal structure among the points of space-time. As the twins paradox shows, the observable behavior of material objects is determined by that structure. And even more dramatically, in general relativity the space-time manifold takes on a life of its own; gravitational waves can exist even in the absence of any material objects, and the presence of material objects influences the structure of space-time.

Attempts have been made to reformulate general relativity in a more relationist manner, in terms only of relations among material objects without commitment to any spatiotemporal structure of vacuum regions. These attempts have not succeeded. One can, of course, simply declare that in the general theory, space-time itself counts as a material entity, but then the argument seems to be only over labels rather than ontology.

Like all empirical theories, relativity is supported but not proven by observation. The spatiotemporal structure cannot be directly observed, but theories of matter couched in terms of the relativistic structure yield testable predictions that can be checked. The general theory, for

example, has been checked by flying an atomic clock around the world and comparing its reading with an initially synchronized clock that remained on Earth. Because the trajectories of the clocks have different relativistic intervals, one can predict that the traveling clock will show a different elapsed time from the clock that remained behind—which it does. There may be other ways to explain the effect, but it is a natural consequence of the relativistic account of space-time structure.

Challenges to the theory of relativity are more likely to come from considerations of the compatibility of the theory with other fundamental physical theories than from direct empirical problems. It is, for example, a still unsolved problem how to reconcile quantum physics with the pure relativistic space-time structure, and another unsolved problem of how to produce a quantum theory of gravity. Most particularly, the observable violations of John Bell's inequality for events at space-like separation are difficult to account for in any theory that has no preferred simultaneity slices in its space-time. So the metaphysician ought not to take the account of space-time provided by relativity as definitive; progress in physics may well demand radical revision of the account of spatiotemporal structure. Still, relativity illustrates how empirical inquiry can lead to the revision of the most seemingly fundamental concepts, even those that were once taken as preconditions for any experience at all.

RELEVANCE (RELEVANT) LOGICS

The conditional, “if ... then ...” (\rightarrow) has been a contentious topic throughout the history of Western logic, and numerous accounts of its behavior have been proposed. One recurrent account (usually called the *material conditional*) is that $A \rightarrow B$ is true just if the antecedent, A , is false or the consequent, B , is true. This account was built into the logic of Frege and Russell, and so came to assume orthodoxy throughout much of the twentieth century (at least where there are no subjunctive moods in the antecedent or consequent). The account has obvious problems, however. It entails, for example, that both of the following are true—which they do not appear to be: “If Melbourne is the capital of Australia, it is in China” (false antecedent), “If there is life on another planet, Canberra is the capital of Australia” (true consequent).

It is natural to suppose that in a true conditional the antecedent must be relevant to the consequent in some way. This idea is packed into the contemporary definition of a relevant logic. A propositional logic is a relevant/relevance (both words are used) logic just if whenever $A \rightarrow B$ is a logical truth A and B share a propositional parameter (variable). (A quantifier logic is relevant if its propositional part is.)

Relevant logics can be of several different kinds. However, one has come to dominate current work in the area. This is the Anderson/Belnap tradition. Axiomatizations of logics (or fragments of logics) of this kind were proposed by Ivan Orlov (1928), Alonzo Church (1951), and Wilhelm Ackermann (1956). But the subject took off with the work of the Pittsburgh school of Alan Anderson and Nuel Belnap in the 1960s and 1970s. Probably the most important system of relevant logic developed by the school was the logic R (though Anderson and Belnap themselves preferred the system E). This contained most of the intuitively correct principles concerning the conditional, but not “paradoxes” such as $(A \& \neg A) \rightarrow B$ and $A \rightarrow (B \rightarrow B)$.

Semantics of various kinds for relevant logics were produced about ten years later by, among others, J. Michael Dunn, Alasdair Urquhart, and Kit Fine. But perhaps the most versatile semantics for relevant logics are the world-semantics developed by the Canberra school of Richard Sylvan (né Routley) and Robert Meyer (who had also been a member of the Pittsburgh school).

The world-semantics of relevant logics may be thought of as extending the possible-world semantics of

modal logic by adding a class of logically impossible worlds—though validity is defined in terms of truth-preservation at just the possible worlds. (This comes out most clearly in the simplified form of the semantics, as later developed by Graham Priest, Sylvan, and Greg Restall.) At a possible world, w , the truth conditions for \rightarrow are the same as those for the strict conditional in the modal logic $S5$:

$A \rightarrow B$ is true at w iff for all worlds, x (possible and impossible), when A is true at x , B is true at x .

At an impossible world, logical truths—for example, of the form $B \rightarrow B$ —may fail. This is achieved by giving the truth conditions of \rightarrow at such a world, w , in terms of a ternary relation, R :

$A \rightarrow B$ is true at w iff for all worlds x, y , such that Rwx , when A is true at x , B is true at y .

These semantics give the base member of the family of logics, B . Other logics in the same family may be obtained by adding constraints on the relation R . The Anderson/Belnap logic, R , is one requiring a number of such constraints. At the time of writing, the nature of R , and so of plausible constraints on it, are still contentious issues.

Another important feature of the semantics of relevant logics is their handling of negation. If $(A \& \neg A) \rightarrow B$ is not to be a logical truth, there must be worlds at which $A \& \neg A$ holds (bringing out the connection between relevant logic and paraconsistent logic). This may be achieved in (at least) two ways. In the first (due originally to Dunn), formulas may take the values *true* and *false* independently (and so may take both or neither). The truth/falsity conditions for negation at a world, w , are then:

$\neg A$ is true at w iff A is false at w

$\neg A$ is false at w iff A is true at w

If A is both true and false at w , so is $\neg A$. So (given the natural semantics for $\&$) $A \& \neg A$ is true (and false) at w .

The second way to handle negation is to treat truth and falsity as usual, but to use the “Routley $*$ ”—invented by Valerie Routley (later Plumwood) and Sylvan. For each world, w , there is a world w^* (usually taken to satisfy the condition that $w = w^{**}$.) The truth conditions for negation are:

$\neg A$ is true at w iff A is false at w^*

If w is w^* , then exactly one of A and $\neg A$ holds at w . But if w is distinct from w^* , and A is true at w and false at w^* , then $A \& \neg A$ is true at w . Again, at the time of writing, the philosophical meaning of $*$ is still a contentious issue.

However the semantics of negation is handled, there will be worlds where A and $\neg A$ hold; and so, assuming the standard behavior of disjunction, where $\neg A \vee B$ holds, for arbitrary B . It follows that the disjunctive syllogism ($A, \neg A \vee B \vdash B$) is invalid. This is significant because it shows that the ramifications of relevant logic spread much wider than may have been thought. In particular, the syllogism does not seem inherently dubious in the same way that the paradoxes of the material conditional are. The invalidity of the syllogism has therefore occasioned much of the criticism attracted by relevant logic. Defenders of relevant logic have replied in various ways.

Philosophical critiques aside, relevant logics have turned out to have a number of interesting mathematical properties. For example, R and some of the other stronger logics (though not the weaker ones) have the unusual property (for a propositional logic) of being undecidable (as shown by Urquhart). Relevant logics are intimately related with algebraic structures called De Morgan lattices, and can also be shown to fit in to the more general class of substructural logics.

RELEVANT ALTERNATIVES

To know a proposition, is it necessary that one is able to rule out every possibility of error associated with that proposition? Notoriously, infallibilism about knowledge—as defended, for example, in early work by Peter Unger (1975)—demands just this and argues on this basis for the skeptical conclusion that knowledge is rarely, if ever, possessed. Intuitively, however, the answer to this question is “no,” in that in everyday life we only demand that knowers rule out those error-possibilities that are in some sense relevant. For example, to know that the bird before me is a goldfinch, I may be required to be able to rule out that it is not some other bird that could be in the area just now, like a jackdaw, but we would not normally demand (at least not without special reasons) that I be able to rule out the possibility that it is not a mechanical goldfinch made up to be an exact replica of the real thing.

If this line of thought is right, then this prompts a relevant alternatives (RA) theory of knowledge that demands that one only needs to be able to rule out all relevant error-possibilities in order to know, not that one is able to rule out all error-possibilities, even irrelevant ones. (A similar view could be applied to other epistemic notions, like warrant or justification. For simplicity, the focus here is on knowledge.) Such a position would thus be a form of fallibilism, which is directly opposed to infallibilism and which thereby counters those versions of skepticism that are based on infallibilist considerations. The task at hand for the RA theorist is to offer a principled account of what makes an alternative relevant.

RELEVANT ALTERNATIVES AND SENSITIVITY

One can find the beginnings of an RA theory of knowledge in the writings of such figures as Ludwig Wittgenstein and John Austin. The first worked out versions of an RA theory, however, can be found in the works of Fred Dretske (1970) and Robert Nozick (1981), who primarily understand knowledge in terms of the possession of beliefs that are sensitive to the truth in the following manner:

Sensitivity

An agent, S , has a sensitive belief in a true contingent proposition, p , if and only if, in the nearest possible worlds in which p is not true, S no longer believes p .

To illustrate this, consider again the example of the goldfinch discussed earlier. Given that the actual world is

roughly as we take it to be, gaining a sensitive belief in the proposition, P, that there is a goldfinch before one is relatively straightforward. All one needs is a true belief in this regard and, in the nearest possible worlds where P is no longer true—where, for example, the goldfinch has flown away leaving behind just an empty branch—one no longer believes that there is a goldfinch there, as presumably one does not. Notice that the relevant possible worlds here are limited and concern error-possibilities (e.g., that there is nothing at all on the branch rather than a goldfinch), which are easy to rule out. A theory of knowledge that treats sensitivity as the key requirement on the acquisition of knowledge is thus in a good position to capture the intuition that ordinarily we do not demand that agents are able to eliminate all possibilities of error before we count them as possessing knowledge.

Interestingly, however, the sensitivity-based approach does treat far-off possible worlds, and thus far-fetched error-possibilities, as sometimes being relevant to the possession of knowledge. Consider, for example, the hypothesis Q, that there is a mechanical goldfinch before one, constructed in such a way as to be indistinguishable to the naked eye from the real thing. When one is faced with what seems to be a goldfinch (and circumstances are, apparently, entirely normal), does one know not-Q? According to the sensitivity-based account of knowledge, this is unlikely because it is difficult to have a sensitive belief in not-Q. After all, to have a sensitive belief in this proposition it would be necessary to have a belief that was not only true in the actual world, but that was also no longer held in the nearest possible worlds in which not-Q is false—that is, those worlds in which Q is true, where one is at present looking at a mechanical goldfinch. The problem is, of course, that, *ex hypothesi*, one would continue to believe that one is looking at a real goldfinch even when one is faced with a mechanical goldfinch, at least unless one conducted special tests (such as capturing the “creature” and cutting it open). So while knowing P is relatively easy, knowing not-Q is hard. And notice that the reason this is the case is because the range of possible worlds, and thus the range of error-possibilities, that is relevant to the determination of one’s knowledge is different in each case.

RELEVANT ALTERNATIVES AND NONCLOSURE

On the face of it, this rendering of the RA theory seems to capture our pretheoretical intuition that in normal circumstances we ought to be able to know that we are looking at a goldfinch even though we are unable to rule out

(i.e., know to be false) the hypothesis that we are looking at a mechanical goldfinch. Nevertheless, this view does have a counterintuitive result, one that both Dretske and Nozick are prepared to accept. This is that the highly intuitive principle that knowledge is “closed” under known entailment (“closure”) has to be rejected. We can roughly formulate closure as follows:

Closure for Knowledge

If an agent, S, knows a proposition, p, and S knows that p entails a second proposition, q, then S also knows q.

For example, if one knows P, then given that one also knows that P entails not-Q (as surely one does), it follows from closure that one must know not-Q. Conversely, of course, if one fails to know the latter proposition, which is what the sensitivity-based approach predicts, then one fails to know the former.

Closure is highly intuitive and yet, as we have just seen, if it holds it would appear to license a restricted form of infallibilism. For although closure does not demand that it is a precondition on knowledge possession that one is able to rule out all possibilities of error, it does demand that one is able to rule out (i.e., know to be false) all those error-possibilities that are known to be inconsistent with what one knows, and this set of error-possibilities, while smaller, is large enough. This point is important, since if the appeal of infallibilism rests on the appeal of closure, then the view is on far stronger ground that one might have initially supposed because of the obvious appeal of the closure principle.

Nevertheless, Dretske and Nozick argue that recognizing that sensitivity is a necessary condition for knowledge highlights why this principle must go, since there are clearly cases, such as the goldfinch example, where one knows one proposition (and thus has a sensitive belief in this proposition) and knows that this proposition entails a second proposition, and yet one lacks a sensitive belief in the entailed proposition and thus fails to know it.

RELEVANT ALTERNATIVES AND CONTEXTUALISM

Although the sensitivity-based proposal has been influential, it does face the problem that it denies the highly intuitive closure principle for knowledge, and this has led some commentators to try to see if there is a way of accommodating the general intuition behind the RA theory in a way that preserves this principle. One of the guiding considerations behind views that try to offer an RA thesis that is consistent with closure is that the Dretske-

Nozick treatment seems to incorporate the idea that closure fails because while sometimes knowledge is hard to attain, sometimes attaining it is relatively straightforward. This tends to suggest that an alternative way of approaching the issue could be to regard knowledge as in some sense context-sensitive, so that one knows both of the target propositions in the closure-based inference relative to one set of epistemic standards (the less demanding ones), but knows neither of them relative to another set of epistemic standards (the more demanding ones). We would thus get a view that incorporates a reading of the RA intuition—because it would remain that not every error-possibility is always relevant to the possession of knowledge—but which was also consistent with closure. This view—known as contextualism about knowledge—is hinted at in an early response to Dretske’s denial of closure written by Gail Stine (1976), and has been developed by Stewart Cohen (1991), Keith DeRose (1995), and David Lewis (1996).

Consider again the goldfinch example. On the Dretske-Nozick view the class of possible worlds, and thus the class of error-possibilities, that is relevant to the determination of knowledge can differ depending on the content of the proposition at issue, which is why in this case the agent comes out as knowing P while failing to know not-Q, despite knowing that the former entails the latter. The reason for this is that when it comes to knowing P only nearby possible worlds are relevant, whereas knowing not-Q brings in farther out possible worlds. Suppose instead, however, that one simply treated the class of possible worlds as fixed in each context, so that the epistemic status of all beliefs—whatever their content—were in that context evaluated relative to those possible worlds. In normal contexts, then, only nearby possible worlds would be relevant, while in more demanding contexts far-off possible worlds would become relevant. This way of understanding knowledge would mean dropping sensitivity as a requirement on knowledge, of course, since there may be no nearby possible worlds in which the target proposition is false (this is, indeed, what we would expect to be the case when it comes to the hypothesis that one is at present looking at a mechanical goldfinch). Nevertheless, the guiding thought here is that so long as the agent’s belief matches the truth in the relevant possible worlds—that is, where the agent believes that proposition, it is true; and where the proposition is not true, the agent does not believe it—then the agent’s belief will be in the market to be counted as an instance of knowledge.

By contextualist lights, then, in contexts where the epistemic standards are low (and thus only nearby possible worlds count as relevant) one will tend to know both P and not-Q, since even one’s belief in not-Q will tend to match the truth (i.e., one believes it in all nearby possible worlds and it is true in all nearby possible worlds). In contrast, in contexts where the epistemic standards are more demanding, and thus where farther out possible worlds become relevant, it will now no longer be the case that one will tend to know either of these propositions. After all, there will be possible worlds, such as the far-off world in which there is a sophisticated plot to deceive people about the presence of goldfinches, in which one’s beliefs in P and not-Q no longer match the truth. Thus, as long as one consistently sticks to a specific epistemic standard then this construal of the RA intuition is not in conflict with closure since, depending on the context at issue, either one has knowledge of both of the target propositions or one has knowledge of neither of them.

RELEVANT ALTERNATIVES AND SAFETY

In more recent work, however, a third rendering of the RA thesis has come to the fore, one that is neither contextualist nor results in the denial of closure. This position—defended, for example, by Ernest Sosa (1999)—holds that far-off possible worlds are always irrelevant to knowledge, whatever the content of the target proposition or the context at issue. Accordingly, one is able to know, for example, both P and not-Q, whatever the context.

This view tends to hold that the key condition that a belief must meet if it is to count as knowledge is that it be safe. Safety can be roughly formulated as follows:

Safety

An agent, S, has a safe belief in a true contingent proposition, p, if and only if, in all nearby possible worlds in which S believes p, p is true.

Notice that contextualists will have to appeal to something like safety to explain how agents can know a proposition like not-Q in epistemically undemanding contexts where there are no nearby worlds in which what is believed is false. The point will be that while such beliefs are not sensitive, since there is no relevant Q-world for them to be sensitive to, they are safe, in that the agent’s belief in not-Q is always true across the relevant possible worlds. What is important about safety for our purposes is that it simply specifies the class of possible worlds that is relevant and leaves the matter at that—there is no room

here for a shift in context that would in turn alter the class of possible worlds, and thus the class of error-possibilities, that is relevant to the determination of knowledge. Accordingly, it will not matter which context one is in. Just so long as one's beliefs that P and not-Q are both safe—as presumably they will be—then one is in a position to know both of these propositions and thus there is no tension with closure.

CONCLUDING REMARKS

There are thus three competing conceptions of the RA intuition in the literature. The first view treats relevance as being determined by the content of the proposition known, and as a result maintains that the closure principle for knowledge fails. The second view treats relevance as being determined by context, and thereby retains closure. Finally, the third view also retains closure, but does so by maintaining an invariant standard of relevance, regardless of the content of the target proposition or of the context at issue.

Duncan Pritchard (2005)

RELIABILISM

Reliabilism is an approach to the analysis of either knowledge or justified belief that makes, in some way or another, the reliability of belief-producing faculties or processes the key notion of epistemic assessment. An early version of a reliabilist theory of *knowledge* was proposed by David M. Armstrong (1973), who thought of knowledge in terms of a reliable thermometer that accurately indicates the correct temperature. A (noninferential) true belief amounts to knowledge, according to Armstrong, if its properties nomically (i.e., via the laws of nature) guarantee its truth. Closely related theories conceive of knowledge as resulting from a counterfactual guarantee of truth. For instance, according to Robert Nozick (1981), knowledge comes about when a subject's belief that p tracks the truth of p, which it does (focusing just on the core of Nozick's theory) if the following condition is met: S would not believe that p if p were false. Alternatively, Fred Dretske (1971, 1981) suggests that a true belief counts as knowledge if the subject possesses a conclusive reason for p. According to this proposal, S knows that p on the basis of a reason, R, if R would not be true unless p were true.

RELIABILIST THEORIES OF JUSTIFIED BELIEF

Turning to reliabilist theories of *justified belief*, there are two main versions to consider: reliable indicator theories, and process reliabilism. A version of the former was developed by Marshall Swain (1979): What makes S's belief that p justified is the belief's being a reliable indication (conceived of in terms of objective probability) of p's truth. In contrast, process reliabilism (reliabilism_{pr}), as advocated by Alvin Goldman (1979), focuses not on the belief itself, but its causal history, or the cognitive process by which it was formed. The basic proposal is that a belief that p is justified if and only if the process by which it was formed is (sufficiently) reliable. On the one hand, perception, memory, and introspection are reliable cognitive processes, typically resulting in justified beliefs and indeed knowledge. Hasty generalization, wild hunches, and wishful thinking, on the other hand, are unreliable processes and invariably produce unjustified beliefs and prevent the formation of knowledge. Moving beyond this initial characterization, an account of reliabilism_{pr} requires refinement as to the question of precisely what determines the reliability of a cognitive process. According to one approach, a process's reliability is fixed by the truth ratio of its actual doxastic output: The greater the ratio of true over false beliefs within the set of beliefs that

make up a process's actual track record, the higher its degree of reliability. As an alternative to such a *track record* conception, William Alston (1995) recommends a *propensity* construal, according to which a process's reliability is determined by, not its actual track record, but what the truth ratio of its output *would be* in an appropriate range of cases.

According to reliabilism_{pr}, as well as other versions of reliabilism, whether S's belief that p is justified, or an instance of knowledge, does not depend—at least not exclusively—on S's evidence relative to p. Reliabilist theories of knowledge and justification must thus be viewed as intended alternatives to evidentialist theories (Chisholm 1989, Conee and Feldman 1985). Nevertheless, in Goldman's defense of reliabilism_{pr}, evidentialist considerations do not completely drop out of the picture. Suppose the following: (i) S forms the belief that p via process C; (ii) C is in fact reliable; and (iii) on the basis of professional testimony, S has reason to believe that C is unreliable. Intuitively, S's belief is not justified. Cases such as that make it doubtful that origination in a reliable process is by itself sufficient for justification. Accordingly, Goldman (1986) supplements his account with a nonundermining clause to the effect that S must not believe, or be in possession of evidence supporting the belief, that the relevant process is unreliable.

In its most radical and challenging manifestation, reliabilism_{pr} asserts that reliable belief formation is both necessary and sufficient for a belief's justification. Alston (1989) defends a moderate version, according to which reliable belief formation is merely necessary for justification. An approach that may be viewed as an alternative to reliabilism_{pr}—virtue epistemology—shifts the focus away from reliable processes to reliable faculties or cognitive virtues, giving rise to the thought that justification and knowledge may be conceived of as resulting from the employment of virtuous faculties (Sosa 1991). A related approach is advocated by Alvin Plantinga (1993). Plantinga's view is that knowledge is generated by properly functioning faculties, where a faculty's proper functioning requires reliability, in addition to adequate design and an orientation towards truth and the avoidance of falsehood.

THE THREE MAJOR PROBLEMS WITH RELIABILISM

Reliabilism_{pr} is confronted with three major problems. The first of these raises the issue of whether production via reliable processes is necessary for justification (Cohen 1984, Ginet 1985). Consider the beliefs of a subject who

is deceived by an evil demon. Because the evidential situation of an evil demon victim is not relevantly different from that of a normal person who has (presumably) by and large justified beliefs, it is commonly agreed that such a victim's beliefs are, just like a normal person's, by and large justified. Alas, the victim's beliefs are, unlike those of a normal person, massively false. The challenge for reliabilism_{pr}, then, is this: The beliefs of an evil demon victim are justified although they are the result of *unreliable* cognitive processes.

There are four ways in which reliabilists can respond. First, they can—implausibly—deny that evil demon victims have justified beliefs. Second, they can deny the relevance of the counterexample, as Alston (1995) does. He argues that the cognitive processes to consider are to be restricted to those that would yield a high truth ratio over a wide range of situations *of the kind one typically encounters*. Third, advocates of reliabilism_{pr} can try to accommodate the counterexample by modifying reliabilism_{pr}. For example, Goldman (1986) introduces normal worlds reliabilism, the basic idea of which is that a belief (in any possible world) is justified if and only if the process by which it was formed is reliable in normal worlds: worlds that correspond to our general beliefs about the actual world. Because perception is reliable in normal worlds, normal worlds reliabilism arguably yields the result that the perceptual beliefs of evil demon victims are justified.

Whether this response succeeds depends on whether the processes by which an evil demon victim forms beliefs can properly be characterized as perceptual, memorial, and so on. After all, at the end of the causal chains from which a deceived subject's beliefs originate, there is the evil demon: not exactly the kind of creature one finds in any normal worlds. So if the belief-generating processes are considered in their entirety, it is hard to tell what their truth ratios in normal worlds would be because such processes are not part of any normal worlds to begin with. Fourth, defenders of reliabilism_{pr} can introduce different concepts of justification. For example, Goldman (1988) distinguishes between strong and weak justification. According to this proposal, the beliefs of evil demon victims are justified in the weak sense, whereas reliabilism is intended to be an analysis of strong justification, the kind of justification that is needed if a true belief is to count as an instance of knowledge.

THE SECOND PROBLEM. The second problem raises the issue of whether origination in a reliable process is sufficient for justification (BonJour 1985, ch. 4). Suppose the following: (i) Norman's belief that p is the result of clair-

voyance; (ii) Norman's faculty of clairvoyance is reliable; and (iii) Norman has no reason to believe that his belief that *p* originated in, or is sustained by, a reliable faculty. Reliabilism_{pr} implies that Norman is justified in believing that *p*, whereas intuitively he seems to be unjustified. In response, reliabilists can deny the intuition underlying the objection—that is, insist that Norman's belief is justified. Alternatively, they can, once again, attempt to accommodate the example by devising a suitable modification. For example, they might consider *ignoring the absence of evidential support* an unreliable cognitive process, and suggest that beliefs whose causal origin includes that process are unjustified. The problem with this suggestion is that it threatens to rob reliabilism_{pr} of its identity by letting it collapse into a disguised version of evidentialism.

THE THIRD PROBLEM. The third problem, known as the “generality problem,” raises the issue of how to individuate the cognitive processes the reliability of which is supposed to determine whether a belief is, or fails to be, justified (Feldman 1985). Suppose a person sees, and thus believes, that the cat is lying on the couch. The process by which this belief is formed could plausibly be classified as perception. More specifically, it could be viewed as an instance of visual perception. Further specification yields further choices: visual perception at a distance of (say) eight feet; visual perception of a medium sized object at a distance of eight feet; visual perception of a medium sized object at a distance of eight feet under daylight illumination. In general terms, the point is that a particular *token* of a cognitive process instantiates many different process *types*. Some of them are reliable, some of them are not. Whether a belief whose justificational status is at issue comes out justified or unjustified will depend on which process type is made the basis of the assessment. The challenge advocates of reliabilism_{pr} face is to give a principled account of how to select the right process type.

Consider perception, an obviously reliable process. But not all perceptual beliefs are justified. Nor are, for that matter, all memorial beliefs, or all visual beliefs, or all auditory beliefs. Sometimes, perceivers fail to take into account undermining evidence, and then beliefs produced by reliable processes fail to be justified. Hence individuating process types using broad categories such as perception, vision, or memory will often yield the wrong results. More specification is clearly required. But too much specification also yields the wrong results. At the extreme end of specification are process types instantiated by one and only one process token; one then

encounters what Richard Feldman (1985) calls the “single case problem.” If such a token results in a false belief, the result will be total unreliability, for the process type's output is false in all cases. If the process token in question results in a true belief, the result will be perfect reliability, for the process type's output is true in all cases. In the former case, the belief will be unjustified no matter what; in the latter case, it will be justified no matter what. This will result in clearly counterintuitive results. Suppose *S* is a paranoid schizophrenic. While riding on the bus, *S*'s paranoia leads him to believe that the bus will blow up. Suppose further that that is in fact true. Let *P** stand for a process type described in such a way that *P** has *one and only one* instantiation: the process token that caused *S*'s belief about the bus. (Such a description can easily be achieved by making reference to properties that uniquely pick out *S* and the circumstances under which *S* formed that belief.) Because *P** is a (perfectly) reliable process, reliabilism_{pr} implies—implausibly—that *S* is justified in believing that the bus will blow up. The problem for advocates of reliabilism_{pr} is this: On the basis of what principled grounds can they claim that *P** is not the process type the reliability of which determines the justificational status of *S*'s belief?

Alston (1995) claims that there is a solution to the generality problem. Regarding the single case problem, he suggests that it does not arise when the track-record conception of reliability is replaced with a propensity conception. Consider again the belief of the paranoid subject that the bus will blow up. On the propensity conception of generality, the process type in question, having precisely one instantiation that led in fact to a true belief, nevertheless counts as unreliable when it is taken into account that beliefs resulting from paranoia tend to be false. Moreover, Alston argues that there are objective, psychological facts of the matter that determine, for each process token leading to a particular belief, which process type this token instantiates. According to Alston, every process token instantiates an input-output function. Each time a belief is formed, Alston claims, there is one and only one input-output pair that is psychologically real. However, Earl Conee and Richard Feldman (1998) respond that, even if one accepts the constraints Alston places on the selection of legitimate process types, there will still be a wide range of process types going from narrow to broad characterizations. As a result, there will be cases of belief formation for which reliabilism_{pr} will not yield a determinable implication about the belief's justificational status.

INTERNALIST AND EXTERNALIST THEORIES

It is common practice to distinguish between *internalist* and *externalist* theories of knowledge and justification. According to internalism about justification, the factors that determine a belief's justificational status (call them "J-factors") must be internal to the subject's mind. Typically, such internality is defined epistemically: An item *x* is internal to *S* if and only if *S* can, merely by reflecting on it, determine whether *x* is present or absent. Internalist theories of justification, then, usually demand that J-factors must be such that their presence or absence is always on reflection recognizable by the subject. As a result of this constraint, justification itself turns into something the presence or absence of which can be recognized upon reflection. According to externalism about justification, J-factors are not subject to any internality constraint. Reliabilism about justification, in its various manifestations, is an externalist theory, for the obvious reason that subjects are not always in a position to determine, solely on the basis of reflection, whether their beliefs are the result of reliable cognitive processes. Consider, again, the victim of an evil demon. Upon reflection, such a victim will think that her perceptual beliefs originate in reliable cognitive processes, when in fact they do not. However, the classification of reliabilism as an externalist theory should not be misunderstood to mean that, according to reliabilism, the reliability of our cognitive processes is completely beyond our ken. To the contrary, there is no reason why reliabilists should deny that, in typical situations when a subject forms, for example, perceptual or memorial beliefs, it should be knowable to the subject, on the basis of presently available evidence, that the beliefs in question have their origin in reliable processes or faculties.

The internalism/externalism issue presents itself in a different form when the object of the dispute is not justification but knowledge. There is broad agreement that knowledge is not, and indeed cannot be, internal in the way in which, according to some, justification is internal. Suppose the following: (i) *S* has a body of excellent evidence, *E*, in support of *p*; (ii) *E* is misleading: *p* is in fact false. Reflecting on whether she knows that *p*, *S* will of course conclude, mistakenly, that she does. Clearly, then, whether or not one knows cannot always be determined upon reflection. Thus it is beyond dispute that knowledge is external. Nevertheless, it would not be inaccurate to say that evidentialists defend an internalist conception of knowledge. According to evidentialists, *S* knows that *p* only if *S* has a good reason for *p*. But whether or not one

has a good reason for *p* is something that is internal to the subject; it is something that can be determined merely by reflecting on one's evidence. Evidentialists, therefore, hold that one of the necessary conditions of knowledge is internal, and thus may be considered internalists about knowledge. Reliabilists, however, are externalists about knowledge, for they typically claim that reliable belief production, suitably qualified, is sufficient for making a true belief an instance of knowledge, thus advocating an account of knowledge without any internalist condition.

The reliabilist, externalist view that the employment of reliable processes or faculties is sufficient for making a true belief thus produced an instance of knowledge that can be supported by citing that very young children and animals possess knowledge, for neither the former nor the latter would seem to be capable of having good reasons in support of their beliefs. The evidentialist, internalist view that one knows only if one possesses a good reason can be defended by pointing out that, upon discovering that a person believes that *p* without having a good reason for *p*, we tend to judge that that person does not know that *p*. Reliabilists, on the one hand, need to come to terms with one kind of fact about our ordinary cognitive practice: people are reluctant to attribute knowledge in the absence of good reasons. Evidentialists, on the other hand, need to come to terms with another kind of fact about our ordinary cognitive practice: people do not hesitate to attribute knowledge to very young children and even such animals as cats and dogs.

CONCLUSION

Even though reliabilist theories are properly classified as externalist, there is no reason in principle why internalists should not acknowledge the relevance, or even fundamental importance of reliability. To begin with, internalists might agree that a true belief counts as knowledge only if it originates in a reliable faculty. Furthermore, Matthias Steup (2004) proposes *internalist reliabilism* as an answer to the question of why sense experience is a source of justification. According to Steup's proposal, what makes sense experience a source of justification is not *de facto* reliability, but *evidence* of reliability. Perception is a source of justification for a subject, *S*, if and only if *S* has, on the basis of track record memories, reason to believe that her perceptual faculties are reliable. According to this proposal, perception is a source of justification even in worlds in which it is in fact unreliable, as long as, on the basis of adequate evidence, it appears to be reliable. According to such an approach, issues of reliability lie indeed at the heart of epistemology, for *S* acquires

knowledge only if S (i) employs a faculty that is in fact reliable, and (ii) possesses evidence of that faculty's reliability.

Matthias Steup (2005)

RELIGION

This entry is not a survey of the various forms that "religion" has taken in human history; rather, it treats the nature of religion as a problem in the philosophy of religion. It will be concerned with attempts to develop an adequate definition of religion, that is, to make explicit the basic features of the concept of religion.

GENERAL DEFINITION AND CHARACTERISTICS

EXAMINATION OF DEFINITIONS. A survey of existing definitions reveals many different interpretations.

"Religion is the belief in an ever living God, that is, in a Divine Mind and Will ruling the Universe and holding moral relations with mankind."
—James Martineau

"Religion is the recognition that all things are manifestations of a Power which transcends our knowledge."
—Herbert Spencer

"By religion, then, I understand a propitiation or conciliation of powers superior to man which are believed to direct and control the course of Nature and of human life."
—J. G. Frazer

"Religion is rather the attempt to express the complete reality of goodness through every aspect of our being."
—F. H. Bradley

"Religion is ethics heightened, enkindled, lit up by feeling."
—Matthew Arnold

"It seems to me that it [religion] may best be described as an emotion resting on a conviction of a harmony between ourselves and the universe at large."
—J. M. E. McTaggart

"Religion is, in truth, that pure and reverential disposition or frame of mind which we call piety."
—C. P. Tiele

"A man's religion is the expression of his ultimate attitude to the universe, the summed-up meaning and purport of his whole consciousness of things."
—Edward Caird

"To be religious is to effect in some way and in some measure a vital adjustment (however tentative and incomplete) to whatever is reacted to or regarded implicitly or explicitly as worthy of serious and ulterior concern."
—Vergilius Ferm

If we take these definitions as attempts to state necessary and sufficient conditions for something to be a religion, it is not difficult to show that none of them is adequate. With respect to necessary conditions, consider Martineau's definition. It is clear that such a belief does not have to be present in a religion. No polytheistic religion recognizes a single divine ruler of the universe; and there are religions, such as Hinayana Buddhism, in which beliefs in personal deities play no role at all. Bradley and Arnold identify religion with morality, but there are primitive societies in which there is no real connection between the ritual system, with its associated beliefs in supernatural beings, and the moral code. The latter is based solely on tribal precedent and is not thought of as either originating with or sanctioned by the gods. If, as would commonly be done, we call the former the religion of the culture, we have a religion without morality. As for McTaggart and Tiele, it seems likely that if we specify "piety" or "feeling of harmony" sufficiently to give them a clear and unambiguous meaning, we will be able to find acknowledged religions in which they do not play an important role. It would seem that we could avoid this only by construing "piety," for example, to cover any state of feeling that arises in connection with religious activities. It does seem plausible to regard some of the definitions as stating necessary conditions, as in Caird and Ferm. However, it is doubtful that these are sufficient conditions. Does any "ultimate attitude" or any "vital adjustment" constitute a religion? As William James points out (*The Varieties of Religious Experience*, Ch. 2), it seems doubtful that a frivolous attitude toward life constitutes a religion, even if it is the fundamental attitude of a given person. And Ferm's overcarefully worded statement would seem to admit any attitude with respect to anything considered important to the ranks of the religious. This would presumably include one's attitude toward one's spouse, toward one's vocation, and, in many cases, toward one's athletic activities. At this point one wonders what has happened to the concept of religion. Many of the definitions are deficient on grounds of both necessity and sufficiency. To return to Martineau, it is quite conceivable that such a belief might be held purely as a speculative hypothesis, without affecting the believer's feelings and attitudes in the way that would be requisite for religious belief. And as for McTaggart, it seems clear that one could from time to time have such a sense of harmony without this being integrated into anything that we would call a religion.

It is noteworthy that most of these definitions stress one aspect or another of religion to the exclusion of others. Thus, Martineau and Spencer represent religion as

some sort of belief or other cognitive state; Frazer, as ritual (conceived in a utilitarian fashion); Bradley and Arnold, as a kind of moral attitude and activity; and McTaggart and Tiele as a certain kind of feeling. One might attribute the failings of these definitions to their one-sidedness. One could hardly expect to get an adequate statement of the nature of so complex a phenomenon as religion, essentially involving, as it does, all these forms of human activity by restricting oneself to belief, feeling, ritual, or moral attitude alone. Caird and Ferm escape this particular failing by concentrating on a comprehensive term such as *attitude* or *adjustment*, which itself embraces belief, feeling, and moral attitude. But, as we have seen, these formulations do not come measurably closer to providing a set of necessary and sufficient conditions.

There are other ways of construing definitions of religion. Instead of taking the above statements as attempts to specify features that are common and peculiar to cases of religion, we might take each of them as an attempt to state the *essence* of religion, that central feature in terms of which all religious phenomena are to be understood. This approach to the matter is explicit in the following statements:

"The essence of religion is a belief in the persistency of value in the world."—Harald Høffding

"The heart of religion, the quest of the ages, is the outreach of man, the social animal, for the values of the satisfying life."—A. E. Haydon

"The essence of religion consists in the feeling of an absolute dependence."—Friedrich Schleiermacher

There are two distinguishable interpretations of claims of this type. They might be interpreted genetically, as accounts of the origin of religion. The claim would then be that what is specified as the essence of religion is the original root from which all phenomena of religion have sprung. Thus, Julian Huxley, like Schleiermacher working with a conception of the essence of religion as a kind of feeling, says, "the essence of religion springs from man's capacity for awe and reverence, that the objects of religion ... are in origin and essence those things, events, and ideas which arouse the feeling of sacredness" (*Religion without Revelation*, p. 111). Similarly starting with Høffding's formulation, we might try to show how typical religious doctrines, rites, and sentiments grew out of an original belief in the persistency of value. However, since we know virtually nothing about the prehistoric origins of religion, speculation in this area is almost completely unchecked by data, and it seems impossible to find

any rational basis for choosing between alternative genetic accounts.

However, we might also give a nongenetic interpretation. Saying that the essence of religion is a feeling of absolute dependence, for example, might mean that the full interrelatedness of the various features of religion can be understood only if we view them all in relation to a feeling of absolute dependence. This claim would be independent of any view of the origin of religion. The difficulty with this is that there would seem to be several different features of religion that could be taken as central—such as ritual, a need for reassurance against the terrors of life, or a need to get a satisfactory explanation of the cosmos—and it is illuminating to view the rest of religion as related to each of these. How is one to settle on a unique essence?

CHARACTERISTIC FEATURES OF RELIGION. Despite the fact that none of the definitions specifies a set of characteristics which is present when and only when we have a religion, or gives us a unique essence, it does seem that they contribute to our understanding of the nature of religion. It appears that the presence of any of the features stressed by these definitions will help to make something a religion. We might call such features, listed below, religion-making characteristics.

- (1) Belief in supernatural beings (gods).
- (2) A distinction between sacred and profane objects.
- (3) Ritual acts focused on sacred objects.
- (4) A moral code believed to be sanctioned by the gods.
- (5) Characteristically religious feelings (awe, sense of mystery, sense of guilt, adoration), which tend to be aroused in the presence of sacred objects and during the practice of ritual, and which are connected in idea with the gods.
- (6) Prayer and other forms of communication with gods.
- (7) A worldview, or a general picture of the world as a whole and the place of the individual therein. This picture contains some specification of an overall purpose or point of the world and an indication of how the individual fits into it.
- (8) A more or less total organization of one's life based on the worldview.
- (9) A social group bound together by the above.

Interrelations of characteristics. Religion-making characteristics do not just happen to be associated in reli-

gion; they are intimately interconnected in several ways. Some of these connections have been indicated, but there are others. For example, the distinction between sacred and profane objects is based on other factors mentioned. It is not any intrinsic characteristic of a thing that makes it a sacred object; things of every conceivable kind have occupied this position—animals, plants, mountains, rivers, persons, and heavenly bodies. Certain objects are singled out as sacred in a given community because they typically arouse such feelings as awe and a sense of mystery, and thus the members of that community tend to respond to these objects with ritual acts. Again, the emotional reaction to sacred objects may be rationalized by conceiving the object to be the habitation or manifestation of a god. The awe aroused by the wild bull led to its being identified with the wild god of intoxication, Dionysus. The very special impression made by Jesus of Nazareth on certain of his contemporaries was expressed by calling him the Son of God. These examples make it sound as if emotional reactions to sacred objects come first and that these reactions are then explained by positing gods as their causes. But it can also happen the other way round. The acceptance of beliefs about the gods and their earthly habitations can contribute to the evocation of awe and other feelings in the presence of certain objects. The members of a religious community are taught to hold certain objects in awe by being taught various doctrines about the gods. Thus, Christians are taught to regard the cross and the consecrated bread and wine with reverence by being told of the Crucifixion and the Last Supper.

A similar reciprocal relationship holds between ritual and doctrine. A doctrine can be introduced as the justification of an already established ritual. Thus, the myth of Proserpine being carried off to the underworld and remaining there half the year seems to have been introduced as an explanation of a preexisting magical fertility cult, in which an ear of grain, perhaps called the corn maiden, was buried in the fall and raised sprouting in the spring. On the other hand, changes in doctrine can engender, modify, or abolish rituals. Beliefs about the divine status of Jesus Christ played an important role in shaping the Christmas festival.

Definition in terms of characteristics. If it is true that the religion-making characteristics neither singly nor in combination constitute tight necessary and sufficient conditions for something being a religion, and yet that each of them contributes to making something a religion, then it must be that they are related in some looser way to the application of the term. Perhaps the best way to put it

is this. When enough of these characteristics are present to a sufficient degree, we have a religion. It seems that, given the actual use of the term *religion*, this is as precise as we can be. If we tried to say something like “for a religion to exist, there must be the first two plus any three others,” or “for a religion to exist, any four of these characteristics must be present,” we would be introducing a degree of precision not to be found in the concept of religion actually in use.

Another way of putting the matter is this. There are cultural phenomena that embody all of these characteristics to a marked degree. They are the ideally clear paradigm cases of religion, such as Roman Catholicism, Orthodox Judaism, and Orphism. These are the cases to which the term *religion* applies most certainly and unmistakably. However, there can be a variety of cases that differ from the paradigm in different ways and to different degrees, by one or another of the religion-making characteristics dropping out more or less. For example, ritual can be sharply de-emphasized, and with it the demarcation of certain objects as sacred, as in Protestantism; it can even disappear altogether, as with the Quakers. Beliefs in supernatural beings can be whittled away to nothing, as in certain forms of Unitarianism, or may never be present, as in certain forms of Buddhism. And, as mentioned earlier, in certain primitive societies morality has no close connection with the cultic system. As more of the religion-making characteristics drop out, either partially or completely, we feel less secure about applying the term *religion*, and there will be less unanimity in the language community with respect to the application of the term. However, there do not seem to be points along these various dimensions of deviations that serve as a sharp demarcation of religion from nonreligion. It is simply that we encounter less and less obvious cases of religion as we move from, for example, Roman Catholicism through Unitarianism, humanism, and Hinayana Buddhism to communism. Thus, the best way to explain the concept of religion is to elaborate in detail the relevant features of an ideally clear case of religion and then indicate the respects in which less clear cases can differ from this, without hoping to find any sharp line dividing religion from nonreligion. (Cf. Ludwig Wittgenstein’s notion of “family-resemblances” among the things to which a term applies.)

An adequate definition of religion should throw light on the sorts of disputes and perplexities that typically produce a need to define religion, such as disputes over whether communism is a religion, and whether devotion to science can be called a man’s religion. So long as we are

dealing with definitions of the simplistic type that we have criticized, these problems are not illuminated. Each party to the dispute will appeal to a definition suited to the position he is defending, and since none of these definitions is wholly adequate, there is an irreducible plurality of not wholly inadequate definitions to be used for this purpose. Person *A*, who claims that communism is a religion, will give, for instance, Caird’s statement as his definition of religion, and person *B*, who denies this, will choose Martineau’s. Obviously, the position of each is upheld by his chosen definition. Hence, it would seem that the only way to settle the dispute is to determine which is the correct definition. However, we have seen that this gets us nowhere; no such definition is wholly adequate.

At this point there is a temptation to brand the dispute purely verbal, a reflection of different senses attached to the word *religion*. It may seem that the disagreement can be dissolved by persuading all parties to use the word in the same sense. But this is a superficial reaction that does not adequately bring out how much the parties to the dispute have in common. In fact, Martineau and Caird represent two contrasting emphases within a common framework. Suppose that *A* and *B* begin with the same paradigm, orthodox Protestant Christianity. But *A* gives greatest weight to the moral-orientation–emotion elements in this paradigm. As long as anything strongly manifests these elements, as long as it serves as a system of life orientation for the individual who is bound to it by strong emotional ties, he will call it a religion. *B*, on the other hand, gives greatest weight to the belief in a personal God and the complex of emotions, ritual, and devotional acts that is bound up with that belief. Thus, although they have basically the same concept of religion, they will diverge in their application of the term at certain points. Once we realize that this is the true situation, we can state the problem in a more tractable form. We can enumerate the religion-making characteristics and determine which of them communism has and in what degree. Then we can proceed to the heart of the dispute—the relative importance of these characteristics. Insofar as there is a real issue between *A* and *B*, once both are in possession of all the relevant facts, it is whether communism is similar to clear cases of religion in the most important respects, that is, whether the respects in which it is like Protestant Christianity are more important than those in which it is different.

TYPES OF RELIGION

In the case of so complex a concept as religion, it is desirable to supplement the very general portrayal of basic fea-

tures with some indications of the varying emphases placed on them in different religions. To do this, we must develop a classificatory scheme.

William James has reminded us that in every religion there is some sort of awareness of what is called divine and some sort of response to this divinity. This being the case, a very fruitful way of classifying religions is to ask in the case of each: "Where is the divine (the object of religious responses) primarily sought and located, and what sort of response is primarily made to it?" In answering these questions for a given religion, the religion-making features most stressed in that religion will also come to light. According to this principle of division, religions fall into three major groups: sacramental, prophetic, and mystical.

LOCATION OF THE DIVINE. In sacramental religion the divine is sought chiefly in things—inanimate physical things like pieces of wood (relics of saints, statues, crosses), food and drink (bread and wine, baptismal water), living things (the totem animal of the group, the sacred cow, the sacred tree), processes (the movements of the sacred dance). This does not mean that the thing itself is responded to as divine, although this can happen in very primitive forms of sacramental religion, called fetishism. Usually the sacred thing is conceived to be the habitation or manifestation of some god or spirit. Thus, the ancient Hebrews treated the elaborate box that they called the Ark of God as the habitation of their god, Yahweh; the Hindus consider the river Ganges sacred to the god Shiva—they believe that Shiva is in some specially intimate relation to that river, and they bathe in its waters to benefit from his healing power. The Roman Catholic finds the presence of God concentrated in the consecrated bread and wine, which, he believes, has been transformed into the body and blood of Christ. At a more sophisticated level the material thing may be taken as a symbol of the divine rather than as its direct embodiment, as in the definition of a sacrament given in the Anglican Book of Common Prayer, "an outward and visible sign of an inward and spiritual grace."

In prophetic religion the divine is thought to manifest itself primarily in human society—in the events of human history and in the inspired utterances of great historical figures. It is not denied that nature issues from the divine and is under divine control, but it is not in nature that God is most immediately encountered. The divine reality is to be discovered in great historical events—the destruction of cities, the rise and fall of empires, the escape of a people from bondage. The hand of God is

seen in these matters because God is encountered more immediately in the lives and the inspired words of his messengers, the prophets, who reveal in their utterances God's nature, his purposes and commands, and derivatively in the sacred books that contain the records of these revelations. Christianity, Judaism, and Islam, the three chief prophetic religions, are sometimes called religions of the book. Here the key term is not *sacrament* but *revelation*. Prophetic religion, unlike the others, stresses the word as the medium of contact with the divine. (An example is the opening of the Gospel of John.) For the ritualist, and still more for the mystic, whatever words he may use, the consummation of his endeavors is found in a wordless communion with the divine. In prophetic religion, however, the linguistic barrier is never let down; it is not felt as a barrier at all.

The center of mystical religion is the mystical experience, which at its highest development dominates the consciousness, excluding all awareness of words, nature, even of the mystic's own self. In this experience the individual feels himself pervaded and transformed by the divine, identified with it in an indivisible unity. The world and all its ordinary concerns seem as naught as the mystic is caught up in the ineffable bliss of this union. It is not surprising that those who have enjoyed this experience, and those who aspire to it, should take it to be the one true avenue of contact with the divine and dismiss all other modes as spurious, or at least as grossly inferior. Rituals and sacraments, creeds and sacred books, are viewed as paltry substitutes, which are doled out to those who, by reason of incapacity or lack of effort, miss the firsthand mystic communion; or else they are external aids that are of use only in the earlier stages of the quest, crutches to be thrown away when direct access to God is attained.

RESPONSE TO THE DIVINE. In sacramental religion, where the divine is apprehended chiefly in material embodiments, the center of religious activity will be found in ritual acts centering on these embodiments. The sacred places, animals, statues, and such, must be treated with reverence, approached and made use of with due precautions; and around these usages tend to grow prescribed rites. Since the sense of the divine presence in certain objects is likely to be enhanced by participation in solemn ceremonials centering on these objects, the religious activity becomes a self-perpetuating system, embodying what is currently called positive feedback.

In sacramental religion, the ritual tends to absorb most of the religious energies of the adherents and to

crowd the other elements out of the center of the picture. Primitive religion, which is strongly sacramental in character, is often unconcerned with moral distinctions; and we might speculate that the progressive moralization of religion is achieved at the expense of ritual preoccupations. We can see this conflict at many points in the history of religions, most notably in the denunciations that the Hebrew prophets directed against the ritual-minded religionists of their day, and in their exhortations to substitute thirst for righteousness for the concern for niceties of ceremony. Even in its highest developments, sacramental religion tends to slacken the ethical tension that is found in prophetic religion. Where sacramentalism is strong in a monotheistic religion, the natural tendency is to take everything in nature as a divine manifestation. If everything is sacred, then nothing can be fundamentally evil; and thus the distinction between good and evil becomes blurred. One of the elements in the Protestant Reformation was a protest against tendencies to blurring of this sort, which took place in the largely sacramental medieval form of Christianity.

The typical response of prophetic religion to the divine is also nicely coordinated with the chief form in which the divine is apprehended. The reaction naturally called for by a message from the divine is acceptance. This involves both an intellectual acceptance of its contents—belief that whatever statements it makes are true—and obedience to the commands and exhortations it contains. Hence, in prophetic religion faith is the supreme virtue, and affirmations and confessions of faith play an important role. This is illustrated by the insistence of such great Christian prophetic figures as Paul and Martin Luther on faith in Christ as both necessary and sufficient for salvation and by the Muslim practice of repeating daily the creed “There is no God but Allah, and Muḥammad is his prophet.” It is important to realize that faith in this sense means far more than the intellectual assent to certain propositions. It also involves taking up an attitude on the basis of that affirmation and expressing that attitude in action. The Jewish prophet Micah expressed the essence of prophetic religion when he said, “What doth the Lord require of thee, but to do justly and to love mercy, and to walk humbly with thy God?” Thus, it would not be incorrect to say that the emphasis in the prophetic response is ethical, providing we do not separate ethics from the believing acceptance of the divine message that is its foundation.

To understand the typical response of mystical religion, we must remember that for the mystic, immediate identification with the divine is of supreme importance.

Therefore he concentrates on an ascetic and contemplative discipline that will be conducive to the attainment and maintenance of that condition. He tends to become involved in abstentions and self-tortures designed to wean him from his attachment to things of this world, and in contemplative exercises designed to withdraw the attention from finite things, leaving the soul empty and receptive to influences from the divine. He will make use of ceremonies and will accede to moral principles insofar as he believes them to be efficacious in furthering his ultimate goal. But ultimately they must go; when union with God has been achieved, they are of no more significance. Thus, like sacramentalism, mysticism tends toward the amoral. Only rarely does either become completely amoral, and then for different reasons. For the sacramentalist, conventional moral distinctions may come to seem unimportant because he views everything as equally saturated with the divine; they seem unimportant to the mystic because every finite object or activity is outside the mystic union, and so all are, in the end, equally worthless. The righteous and the wicked are equally far from the true religious goal. While united with God, one does not act.

PLACE OF DOCTRINE. Finally, we may compare the three types of religion with respect to the status of beliefs and creeds. Since faith is central for prophetic religion and since the word is stressed as the primary medium of divine manifestation, it is not surprising that in prophetic religion, creed and doctrine are emphasized more than in the others. Mystical religion, at its purest, is indifferent to matters of belief and doctrine. The mystical experience and the divinity it reveals are often regarded as ineffable, not to be expressed in human language; hence, mystics tend to reject all doctrinal formulations as inadequate. At best, a mystic will admit that some formulations are less inadequate symbols of the unutterable than are others. Thus, in such predominantly mystical groups as the Sufis and the Quakers, little or no attempt is made to enforce doctrinal conformity. And in an extreme form of mysticism, like that of Zen Buddhism, any doctrinal formulation is discouraged. Sacramental religion occupies a middle ground in this respect. In its more primitive forms, it is often extremely indefinite about belief. It has been said that primitive man “dances out his religion.” Certainly the elaboration of ritual in primitive religion far outstrips the associated theory. The primitive will often possess an incredibly detailed set of ritual prescriptions but have only the haziest idea of what there is about the nature or doings of the gods that makes them appropriate. In its more developed forms, sacramental theology

becomes more definite, but it is still true that to the extent that a religion is preoccupied with a sacramental approach to the divine, it is more impatient than prophetic religion with doctrinal subtleties.

We can coordinate this classification with the list of religion-making characteristics by pointing out that sacramental religion stresses sacred objects and ritual, prophetic religion stresses belief and morality, and mystical religion places chief emphasis on immediate experience and feeling.

CONCRETE APPLICATION. When we come to apply our scheme to particular cases, we must not suppose that any religion will fall completely in one class or another. In fact, it is better not to think of types of religions, but of religious tendencies that enter in varying proportions into the makeup of any actual religion. However, we can usually say that one tendency or another predominates in a given religion. Thus, Buddhism and philosophical Hinduism are predominantly mystical; Judaism, Islam, and Confucianism are primarily prophetic; and popular Hinduism, in company with all polytheistic and primitive religions, is primarily sacramental. Often a religion that begins with a definite bent will admit other elements in the course of its development. Islam, which began as the most severely prophetic of religions, has developed one of the world's most extreme groups of mystics in the Sufis, who are completely out of harmony with the spirit of Muḥammad, no matter how they may continue to express themselves in his phrases. Again, in Tibet, Buddhism has undergone a development quite foreign to its founder's intentions, blossoming into an extremely elaborate sacramentalism.

Christianity furnishes a good opportunity to study the intermingling and conflict of the different tendencies. It began as an outgrowth of Jewish prophecy, but in the process of adapting itself to the rest of the Western world it took on a considerable protective coloration of both the sacramental and mystical, and these aspects have remained with it throughout its career. Christian mysticism presents a good example of an element existing in a religion that is dominated by another element. As the price of toleration, Christian mystics have had to pay lip service to the official theology and to the prophetic moral element; and as a result, mystic thought and practice in Christianity have seldom received the extreme development found in India. In those cases where the mystical spirit has burst the fetters, as with Meister Eckhart, official condemnation has often resulted.

Looking at Christianity today, it can be said that although it is predominantly a prophetic religion, as compared with Hinduism and Buddhism, with respect to its internal divisions the Catholic wing (both Roman and Greek) tends more toward the sacramental, while the Protestant is more purely prophetic, with mysticism appearing sporadically throughout. In Catholicism the elaborateness of prescribed ceremonies, the emphasis on the necessity of material sacraments for salvation, and the insistence on a special status for consecrated priests are all typically sacramental. In Protestantism the emphasis on the sermon (the speaking forth of the Word of God) rather than on ritual, the emphasis on the Bible as the repository of divine revelation, and the moral earnestness and social concern are all earmarks of the prophetic spirit. Bibliography

Friedrich Schleiermacher, *On Religion*, translated by John Oman (New York: Harper, 1958), and *The Christian Faith*, translated by H. R. Mackintosh (Edinburgh, 1956), contain classic statements of the view that religion is essentially a mode of experience. A more recent statement of this point of view that emphasizes mystical experience is in W. T. Stace, *Time and Eternity* (Princeton, NJ: Princeton University Press, 1952). The moral aspect of religion is stressed in Immanuel Kant, *Religion within the Limits of Reason Alone*, translated by T. M. Greene and H. H. Hudson (La Salle, IL: Open Court, 1934), and in John Baillie, *The Interpretation of Religion* (New York: Scribners, 1928). Conceptions of religion from the standpoint of philosophical naturalism are to be found in Auguste Comte, *A General View of Positivism* (London, 1865); Ludwig Feuerbach, *The Essence of Christianity*, translated by George Eliot (New York: Ungar, 1957); George Santayana, *Reason in Religion* (New York: Scribners, 1905); John Dewey, *A Common Faith* (New Haven, CT: Yale University Press, 1934); and Erich Fromm, *Psychoanalysis and Religion* (New Haven, CT: Yale University Press, 1950). Stimulating discussions, not so easily classified, are Henri Bergson, *The Two Sources of Morality and Religion*, translated by R. Ashley Audra (New York: Holt, 1935); William James, *The Varieties of Religious Experience* (New

York: Longman, 1902); Josiah Royce, *The Sources of Religious Insight* (New York: Scribners, 1912); John Oman, "The Sphere of Religion," in *Science, Religion and Reality*, edited by Joseph Needham (New York: Macmillan, 1925); and Alfred North Whitehead, *Religion in the Making* (New York: Macmillan, 1926). Important discussions from the social sciences include Émile Durkheim, *The Elementary Forms of the Religious Life*, translated by J. W. Swain (London: Allen and Unwin, 1915), and Bronisław Malinowski, *Magic, Science, and Religion* (Garden City, NY: Doubleday, 1954). James H. Leuba, *A Psychological Study of Religion* (New York: Macmillan, 1912), and Julian Huxley, *Religion without Revelation* (New York: Harper, 1958), provide extensive critical discussion of a wide variety of definitions, as well as presenting original conceptions.

RELIGION, NATURALISTIC RECONSTRUCTIONS OF

In philosophy a naturalist is one who holds that there is nothing over and above nature. A naturalist is committed to rejecting traditional religion, which is based on beliefs in the supernatural. This does not necessarily carry with it a rejection of religion as such, however. Many naturalists envisage a substitute for traditional religion that will perform the typical functions of religion without making any claims beyond the natural world. We can best classify naturalistic forms of religion in terms of what they take God to be—that is, what they set up as an object of worship. In traditional religion the supernatural personal deity is worshiped because he is thought of as the zenith of both goodness and power. More generally, we can say that religious worship is accorded to any being because it is regarded as having a controlling voice in the course of events and at least potentially exercising that power for the good. This suggests that to find a focus for religious responses in the natural world, we should look for a basic natural source of value. Forms of naturalistic religion differ as to where this is located. Broadly speaking, achievements of value in human life are due to factors of two sorts: (1) man's natural endowments, together with the deposit of his past achievements in the cultural heritage of a society, and (2) things and processes in nonhuman nature on which man depends for the possibility of his successes and, indeed, his very life. Most naturalists locate their religious object primarily on one or the other side of this distinction, although some try to maintain an even balance between the two.

The first factor is stressed most by those who are called religious humanists. This group includes Ludwig Feuerbach and Auguste Comte in the nineteenth century and John Dewey and Erich Fromm in the twentieth. Of these men Comte has been the most influential.

COMTE

In Comte's view, it is to humanity that the individual man owes everything that he is and has. It is because he shares in the general biological and psychological capacities of human nature that he is able to live a human life. And the men of a given generation are able to lead a fully human life because of the labors of their predecessors in building up their cultural heritage. Moreover, according to Comte, the service of humanity, in the many forms this can take, is the noblest ideal that could be proposed to an individual; and humanity, unlike an omnipotent God, needs this service. Thus, Comte proposed to set up a religion of

humanity with man, viewed as a unitary though spatiotemporally scattered being, as the object of worship.

Unlike many naturalists Comte was not at all vague about the detailed functioning of his proposed religion. He was impressed with the ritual structure of Roman Catholicism and took it as his model. For example, in the analogue of baptism, the sacrament of presentation, the parents would dedicate their child to the service of humanity in an impressive public ceremony. Public observances were to be reinforced by the regular practice of private prayer, on which Comte laid the greatest stress. A person was to pray four times daily, with each prayer divided into a commemorative and a purificatory part. In the first part one would invoke some great benefactor of humanity; by reflecting gratefully on his deeds, one would be inspired to follow his example, and one's love of humanity would thus be quickened. The purificatory part would give solemn expression to the noble desires thereby evoked; in it the individual would dedicate himself to the service of humanity. Other rituals included a system of religious festivals and a calendar of the saints of humanity that provided the material for the prayers on each day of the year.

Some idea of the religious fervor generated in Comte by the contemplation of humanity may be gained from this quotation from *A General View of Positivism*:

The Being upon whom all our thoughts are concentrated is one whose existence is undoubted. We recognize that existence not in the Present only, but in the Past, and even in the Future: and we find it always subject to one fundamental Law, by which we are enabled to conceive of it as a whole. Placing our highest happiness in universal Love, we live, as far as it is possible, for others: and this in public life as well as in private; for the two are closely linked together in our religion; a religion clothed in all the beauty of Art, and yet never inconsistent with Science. After having thus exercised our powers to the full, and having given a charm and sacredness to our temporary life, we shall at last be forever incorporated into the Supreme Being, of whose life all noble natures are necessarily partakers. It is only through the worship of Humanity that we can feel the inward reality and inexpressible sweetness of this incorporation. (p. 444)

Comte had considerable influence in his lifetime, and a few functioning parishes of his religion of humanity sprang up. They have not survived, however, and a revival in our time hardly seems likely. In the twentieth

century, reeling under the impact of two world wars and the hourly expectation of the death knell of civilization, we are not inclined to grow misty-eyed over humanity. Recent humanists have tended to be more critical in their reverence. The latest trend is to single out the more ideal aspects of man—his aspirations for truth, beauty, and goodness—for religious worship. Or the emphasis shifts from man as he actually exists to the ideals that man pursues in his better moments. Thus, in his book *A Common Faith*, John Dewey defines God as “the unity of all ideal ends arousing us to desire and action” (p. 42).

DEWEY

Unlike Comte, Dewey has no interest in developing an organized naturalistic religion. It would seem that religious organization and religious ritual are too closely associated in his mind with the supernaturalism that he rejects. For Dewey the important thing is the religious quality that experience can assume under certain conditions. Any unification of the whole self around the pursuit of an ideal end is religious in quality. Dewey is emphatic in insisting that this is a quality, rather than a kind, of experience. Whenever a person is thoroughly committed to the pursuit of any ideal, be it scientific, social, artistic, or whatever, his experience attains the kind of fulfillment that has always been characteristic of what is most valuable in religion. According to Dewey, in traditional religion this quality has been encumbered and obscured by irrelevant trappings, particularly the theological dogma in terms of which it has been pursued. In the past, self-integration in the pursuit of the ideal has been thought of as service of God, unity with God, or submission to God's will. It is Dewey's conviction that the religious quality can be more effectively sought if the quest is not carried on under this banner. To reflective men, supernaturalistic dogma will always appear dubious at best. If the quest for self-integration in the service of the ideal is too closely tied to theology, it will be endangered when the theology is rejected as rationally groundless. Moreover, insofar as the theology is taken seriously, it diverts attention from the active pursuit of the ideal. Worse, the assurance that the good is already perfectly realized in the divine nature has the tendency to cut the nerve of moral effort; in that case it is not up to us to introduce the good into the world. Thus, Dewey's main concern as a philosopher of religion is to redirect religious ardor into the quest for a richer quality of human life rather than to construct a framework for a naturalistically oriented religious organization.

There is no developed naturalistic philosophy of religion that stresses the nonhuman side of the natural sources of value to the extent to which Comte stresses the human side. (Though we can find this in literature, notably in Richard Jeffries, who had a kind of religious intoxication with inanimate nature without, however, conceiving of it as suffused with a spiritual being or beings. This is a naturalistic counterpart of the nature worship of ancient Greece, just as Comte's religion of humanity is a naturalistic counterpart of an ethical monotheism like Christianity.) However, there is a marked tendency among contemporary naturalists to emphasize the nonhuman side much more than Comte or Dewey. Good examples of this are the liberal theologian Henry Nelson Wieman and the biologist Julian Huxley, who in his book *Religion without Revelation* has made the most coherent and comprehensive recent attempt to sketch out a naturalistically oriented religion.

HUXLEY

According to Huxley's conception, religion stems from two basic sources. One is man's concern with his destiny—his position and role in the universe and their implications for his activity; the other is the sense of sacredness. Following Rudolf Otto, Huxley thinks of the sense of sacredness as a unique kind of experience that is an intimate blend of awe, wonder, and fascination; this mode of feeling arises spontaneously in reaction to a wide variety of objects and situations. Religion, then, is a social organ for dealing with problems of human destiny. As such it involves a conception of the world within which this destiny exists, some mobilization of the emotional forces in man vis-à-vis the world thus conceived, some sort of ritual for expressing and maintaining the feelings and attitudes developed with respect to the forces affecting human destiny, and some dispositions with respect to the practical problems connected with our destiny. The sense of sacredness enters into the second and third of these aspects. As Huxley sees it, a way of dealing with problems of human destiny would not be distinctively religious if it did not stem from and encourage a sense of the sacredness of the major elements in its view of the world, man, and human life.

Huxley, as a thoroughgoing naturalist, holds that the supernaturalistic worldview in terms of which religion has traditionally performed its functions is no longer tenable in the light of modern scientific knowledge. Moreover, he thinks that it is possible to develop a full-blown religion on a naturalistic basis. As the intellectual basis for such a religion, Huxley puts forward "evolutionary natu-

ralism," a view of the spatiotemporal universe, inspired by modern biology and cosmology, in which the universe is conceived of as an indefinitely extended creative process, always tending to higher levels of development, with all the sources and principles of this creativity immanent in the process. The basic role of man is to be the chief agent of this evolutionary advance on earth through the application of his intelligence to the problems of life on Earth and through the building of a harmonious and stable community. A religion based on these conceptions will be focused on an object of worship that is a construct out of all the forces affecting human destiny, including basic physical forces as well as the fundamental facts of human existence and social life. God, then, will consist of all these factors, held together by the feeling of sacredness with which they are apprehended. As a start toward conceiving this assemblage as a unified object of worship, Huxley presents a naturalistic version of the Christian doctrine of the Trinity. God the Father is made up of the forces of nonhuman nature. God the Holy Ghost symbolizes the ideals toward which human beings at their best are striving. God the Son personifies human nature as it actually exists, bridging the gulf between the other two by channeling natural forces into the pursuit of ideals. And the unity of all the persons as one God represents the fact that all these aspects of the divine are intimately connected.

Many thinkers, atheists as well as theists, take a dim view of all these proceedings. Since the theists' lack of enthusiasm stems from obvious sources, let us concentrate on the atheists. The issues here are normative or evaluative rather than factual. Comte and Huxley as philosophers of religion are not, with perhaps minor exceptions, making any factual judgments with which other naturalists might disagree because they are making no factual judgments at all beyond their basic commitment to naturalism. If a man like Bertrand Russell or Jean-Paul Sartre disagrees with Huxley, he differs about the value of what Huxley is proposing. His low evaluation may have different bases. First, he may feel that man or the basic forces of nature constitute too pallid a substitute for the God of theism to afford a secure footing for the distinctively religious reactions of reverence, adoration, and worship. A man like Huxley might, for his part, interpret this as a reflection of a suppressed hankering after the old supernatural deity. Second, Russell or Sartre may turn this charge on Huxley and maintain that one searches for an object of worship within nature only because he has not sufficiently emancipated himself from the old religious orientation and that this religion of evolutionary naturalism represents an uneasy compromise between religious and secular orientations. It seems clear

that there is no one objective resolution of such disputes. People differ in such a way that different total orientations will seem congenial to people with different temperaments and cultural backgrounds. It is perhaps unfortunate, on the whole, that many people need to find something fundamentally unworthy in every other religion in order to find a firm attachment to their own religious positions, although it is undoubtedly true that religious discussions are more lively than they would be if this were not the case.

RELIGION, NATURALISTIC RECONSTRUCTIONS OF [ADDENDUM]

CONTEMPORARY NATURALISTIC RELIGION

What should one contrast nature with? The supernatural, maybe? What is meant here by supernaturalism is the thesis that the divine is different in kind from familiar things and persons; and/or that there are divine interventions that are contrary to the laws of nature. If this is the relevant contrast then naturalistic religion requires merely that God be taken as either a person or a community of persons. God is then like humans, although infinitely more powerful, and acts in the world in whatever way people act when they exercise their freedom. Such anti-

supernaturalism is weaker than naturalism as understood by contemporary philosophers, who would balk at calling the dualist Richard Swinburne (2004), the idealists Timothy Sprigge (1983) and John Foster (2004), or even the nonreductive physicalist Peter Forrest (1996) naturalists. This suggests that naturalism is to be contrasted not merely with the supernatural but also with anthropocentric *Metaphysics*, which takes consciousness and agency as fundamental features of reality that may be used to explain but must themselves be accepted without explanation. Naturalism in this strong sense is unlikely to support the humanist attitudes of Auguste Comte or John Dewey, but coheres well with Julian Huxley's evolutionary naturalism.

DEEP ECOLOGY

The most widespread contemporary naturalistic movement with religious tendencies is deep ecology, which typically goes beyond an attitude of aesthetic appreciation of—and scientific interest in—life on earth, to attitudes of reverence and self-sacrifice (Naess 1989). Combined with a suitable metaphysical system this could be a genuinely naturalistic religion, although neopagan movements such as Wicca tend to incorporate belief in the supernatural. Two such metaphysical systems are process theology and pantheism.

PROCESS PHILOSOPHY

The process philosophy of Alfred North Whitehead, Charles Hartshorne, and most recently David Ray Griffin (2001) can support either a liberal theistic religion or deep ecology. Process philosophy counts as naturalistic because it is biocentric rather than anthropocentric, in that it relies on preconscious sensitivity to the environment (prehension) and final causation. For that reason the God of process philosophy is immanent in the processes of the natural world, resulting in something similar to, although less austere than, Huxley's evolutionary naturalism. A chief objection to process philosophy is that we no longer have a theoretical need for either prehension or final causes even in biology.

PANTHEISM

The universe as a whole or, perhaps better, the natural order is sufficiently awe-inspiring to ground some religious attitudes. So pantheism can form the basis of a naturalistic religion (Levine 1994). Like any religion this has metaphysical commitments: either the existence of the universe as a whole or the existence of laws of nature, but neither of these commitments would worry most naturalists.

THE AFTERLIFE

Much religious motivation (for good and ill) lies in the belief in an afterlife. Does naturalism cohere with this belief? Granted that if there is a God concerned about individuals then there is not much problem, for there are ways God could ensure an afterlife without miracles and without there being souls (van Inwagen 1992). However, a pantheist God that just is the natural order will not be concerned about individuals, whereas the God of process philosophy might well lack the power required to be providential. Frank J. Tipler (1996) has suggested that in the distant future sentient beings will be able to reconstitute all the lives of those who have died. In his version all possible lives seem to get reconstituted, which prevents any of them being the same as early twenty-first century people. But one might surmise that there are traces of actual lives that could be used to reconstitute only those who have actually lived. A less far-fetched naturalistic account of the afterlife is based on the many worlds interpretation of quantum theory. For if there are many parallel universes and every physically possible event occurs in some of them, then in some of them it seems humans survive anything (Price 1996, ch. 9; Lewis 2004). The chief problem with such scenarios is over-survival, that is, at each moment each person divides into millions of successors.

CONCLUSION

Not surprisingly the more narrowly naturalism is understood the more drastic a naturalistic reconstruction of religion must be. At one extreme, anti-supernaturalism sits comfortably with all but conservative religious movements. At the other, naturalists might reject even the biocentrism of process thought and be left with only a rather austere pantheism.

RELIGION, PSYCHOLOGICAL EXPLANATIONS OF

In the seventeenth and eighteenth centuries the chief impact of science on religion came from the revised picture of the cosmos that emerged from developments in astronomy and physics. In the nineteenth century the impact was from the changed view of the history of life on Earth that was presented by geology and evolutionary biology. In the twentieth century the social sciences had the greatest impact on religion, although of a different nature. Physics and biology worried theologians because they introduced theories about the cosmos, life, and man that were at variance with beliefs intimately bound up with the religious tradition, such as the special creation of man. The impact of the social sciences, on the other hand, comes not from theories that contradict basic religious doctrines but from explanations of religion itself that seem to rob it of its significance.

Since the nineteenth century numerous ideas have been put forward as to the psychological and sociological factors that are responsible for religion. The most important of these are (1) the Marxian theory that religion is one of the ideological reflections of the current state of economic interrelations in a society; (2) the similar, but more elaborately developed, theory of the sociologist Émile Durkheim that religious belief constitutes a projection of the structure of society; and (3) the Freudian theory that religious belief arises from projections designed to alleviate certain kinds of unconscious conflict. These are all scientific explanations in that they trace religion to factors wholly within the world of nature, and hence they

are, at least in principle, subject to empirical test. Concentration on one of these, the Freudian, will enable us to illustrate the philosophical problems raised by such explanations.

THE FREUDIAN EXPLANATION

The Freudian account begins with certain similarities between attributes of and attitudes toward a personal deity, on the one hand, and the small child's conception of and mode of relating to his father, on the other. In both cases the superior being is regarded as omnipotent, omniscient, inscrutable, and providential. In both cases the individual reacts to this superior being with utter dependence, awe, fear of punishment, and gratitude for mercy and protection. These parallels suggest, though they do not prove, that the original model for the conception of God is to be found in the infantile conception of one's parents, and that the almost universal inclination to believe in personal deities is to be traced to psychological remnants of the infantile situation. According to Sigmund Freud, these remnants are mostly the result of the Oedipal conflict. According to his theory, around the age of four the boy (restricting ourselves to the male for simplicity of exposition) comes to desire his mother sexually and to regard his father as a rival. Reacting more or less to actual indications, the boy becomes so afraid of the father's hostility, and also so afraid of losing his love, that he not only abandons his sexual aims but also represses the entire complex of desires, fears, and conceptions. This complex remains, in greater or lesser intensity, in the unconscious; and it is because a supernatural personal deity provides an external object on which to project it that men have as much inclination as they do to believe in such a being and to accept the attitudes and practices that go with this belief.

To understand what the projection does for the individual, we must recognize that the repressed material involves severe conflict between tendencies to rebel against the father and tendencies to submit to the father, and between the Oedipal desires and the standards that would be violated by satisfying those desires. Projection of this material onto an external deity reduces distress in several ways. First, the externalization of the problem provides some relief. Instead of being plagued by mysterious discomfort, the individual is faced with a clear-cut opposition between various desires of his own and a forbidding external person. Second, there is less conflict because the external figure is so powerful as to seriously weaken the rebellion, and he is so idealized as to render resentment and hostility less appropriate. Third, there are

various mechanisms provided for dissipating the guilt over sexual desire for the mother and hostility toward the father. Confession, penance, and renunciations of various kinds afford socially approved means for relieving this guilt and counteracting its crippling influence.

People are more receptive to religious belief at some times than at others. Freud explains this in terms of the mechanism of regression. When a person encounters severe difficulties and frustrations at one stage of life, he tends to regress psychologically to an earlier stage at which these problems did not exist. Thus, when an adult is particularly hard pressed, there is generally some reinstatement of earlier modes of thinking, feeling, and relating to the environment. This means that the Oedipal material in the unconscious will become more intense and closer to the surface, while at the same time the person is more likely to engage in the childish practice of projection.

Thus, according to Freudian theory, an individual's tendency to accept belief in a supernatural personal deity (together with the other aspects of religious activity and involvement) is at least partly caused by a tendency to project a childhood father image existing in the unconscious, this projection normally following a regression set off by a current problem of adjustment and serving to alleviate unconscious conflicts and unconscious guilt. It is clear that, at best, this is only a partial explanation of religious belief. For one thing, it presupposes the prior existence of the religious ideas in the culture; at most, it is an explanation of the individual's readiness to accept these ideas when they are proffered.

Freud tried to supply this lack by developing a parallel theory of the development of religion in society. According to this theory, religion develops as a projection of a psychological complex that results from unconscious racial memories of a primal murder of the tyrannical father figure of a "primal horde." Cultural development is thus treated along the same lines as the development of the individual; something like a "collective unconscious" is posited in which psychic material can be transmitted in an unconscious form from one generation to another. However, these ideas have never won any considerable degree of acceptance, and in discussing Freud we can concentrate on his account of the psychological basis of religion in the individual.

CRITICISM OF FREUDIAN EXPLANATION

With respect to any scientific explanation of religion, there are two questions to be raised. (1) What reason is

there to accept it? (2) If it is true, what bearing does it have on the truth, value, or justifiability of religion? It is the second question that specially lies within the province of the philosophy of religion.

It is clear that the Freudian explanation does not imply that the beliefs of religion are false; Freud himself recognized this, though not all Freudians do. But it is often assumed that the success of any explanation of religion in terms of factors within the natural world would show that we do not need to bring anything supernatural into the explanation, and hence would seriously weaken religion's claims to credibility. However, this depends on how these claims were made. If religion is based solely on divine revelation, then the fact that we can give an adequate explanation of religion without bringing in divine activity, revelatory or otherwise, seriously affects—though it does not conclusively disprove—the claim that certain beliefs are true because they are communicated to man by God. But if rational arguments are advanced in support of religious doctrine, such as the classical arguments for the existence of God, then whatever force these arguments have is in no degree lessened by the fact—if it be a fact—that the psychological basis for religion is as Freud supposed. Of course, if the Freudian mechanisms constitute a necessary as well as sufficient condition of religious belief, then it follows that no one has any good reason for these beliefs. If anyone did have a good reason, that would itself be a sufficient condition of the belief, and this would show that it is possible to have the belief without needing to project an unconscious father image. However, it is almost inconceivable that we should show that projection is a necessary condition of belief. At most, we could hope to show that there is some correlation between degree of unconscious Oedipal conflict and firmness of religious belief. Showing that a certain set of natural factors is one of the things that can produce religious belief may well nullify certain ways of supporting the beliefs, but it could hardly show that no adequate rational grounds could be produced.

There is another way in which it has been thought that the Freudian theory of religion carries with it a negative evaluation of religion. The particular causal factors to which Freud traced religion are of a sort associated with undesirable patterns of organization. To regard religion as caused by these factors is to class it with neurotic and infantile modes of behavior, and as such it is hardly worthy of serious consideration. In this respect, too, the psychoanalytic explanation is typical. One can imagine an explanation that traces religious activity to evaluatively neutral natural factors, such as patterns of neural

activity in the brain, but all the explanations in the field trace religion to states and activities that are more or less irrational, immature, or unworthy. Projection is involved in all the theories cited at the beginning of this article; the Marxist theory adds the point that religion is used by the dominant class to provide illusory consolations to those being exploited.

To be clear on this issue, we must distinguish the different forms these claims can take. Psychoanalytic literature is often simply an enumeration of similarities between religion and compulsion neuroses, such as firm attachment to rituals without having a rational explanation of the attachment. However, the similarity in itself proves nothing. A scientist “obsessed with an idea” also exhibits marked similarities to a compulsion neurotic, but this has no implications for the value of his work. The more important claim has to do with the causal factors said to underlie religion. Here, too, we must distinguish between (1) the claim that some neurotic condition is always or generally among the factors producing attachment to a religion, and (2) the claim that the causal basis of such attachment is markedly similar to the basis of recognized neuroses. There is no real evidence for the first claim. Controlled studies on the required scale have never been carried out. As for the second, we must ask how similar the causal basis is and what implications we are to draw from whatever degree of similarity exists. The mere fact that religion involves projection as a relief from unconscious conflict is not sufficient ground for labeling religion, in Freud's terms, “the universal obsessional neurosis of mankind.” We must distinguish between pathological and healthy resolutions of unconscious conflict.

The anti-Freudian psychoanalyst Carl Jung, in terming religion an alternative to neurosis, expressed his belief that it is a healthy outcome. The basic issue involved here concerns the definition of “neurosis.” If we define it in terms of a certain causal basis, then it may be that according to the Freudian theory, religion is, by its very nature, a form of neurosis. But then it remains an open question whether or not it is a desirable, justifiable, or realistic mode of activity. If neurosis is defined in this way, we may have to distinguish between good and bad neuroses. If, on the other hand, we accept common usage and build a negative evaluation into the definition of neurosis (by having as a necessary condition of neurosis that it make a satisfactory adjustment to one's environment difficult), then it would no longer be an open question whether religion, if neurotic, is a good thing. But with this concept of neurosis, we have a much stronger thesis, which calls for evidence that has not yet been pro-

vided. No one has shown that in general religious believers are less able to establish satisfying personal relations and less able to get ahead in their work than are nonbelievers. Even if this were shown, there would be further problems of a very sticky sort. The believer might complain that restricting “the environment” to the natural environment is question-begging. He would say that whatever the bearing of religious attachment on getting along in human society, it is essential to adequate adjustment to God and his demands. To ignore this aspect of “the environment” is to employ a criterion of adjustment that presupposes the falsity of religious beliefs.

Similar comments apply to the idea that the psychoanalytic theory implies that religion is infantile and hence unworthy of mature men. It is true that the way a religious man relates himself to God is in many ways similar to the way a small child relates himself to a father. But whether or not this is a mature, realistic mode of activity is wholly a function of whether there really is such a God. If there is, then this is the only reasonable stance to take. Hence, to condemn religion on these grounds is to presuppose the falsity of its beliefs.

Thus, there are many gaps in any line of reasoning that tries to derive a negative evaluation of religion from a causal explanation of religion in psychological or sociological terms. If a person does not feel that he has a firm basis for his religious beliefs, then looking at religion in a Freudian or Marxian light may well lead him to give up his beliefs. More generally, we can say that Freudian or Marxian theory does not provide an intellectual atmosphere in which one would expect religious belief to flourish; but it does not appear that these theories, as so far developed, are in any way logically incompatible with the truth, justifiability, and value of traditional religion.

RELIGION, PSYCHOLOGICAL EXPLANATIONS OF [ADDENDUM]

During the last few decades of the twentieth century scientific ability to explore the brain directly increased dramatically, so neuroscientific discoveries during the period resulted in a broadening of perspectives from which psychological explanations of religion may be given. First, the ideological impasse on method between behavioristic and psychoanalytic or introspective approaches in psychology yielded to more pragmatic heterophenomenological (Dennett 2003) or neurophenomenological (Varela, Thompson, and Rosch 1991) methods for investigating mental states. Second, Platonic and Cartesian views of emotion as inherently irrational and subversive of productive cognitive functioning were contested by studies that showed that absence of emotion produced a cognitively dysfunctional Phineas Gage, not a pure-minded Philosopher King (Damasio 1994). Third, the Enlightenment notion of a person as an isolated, autonomous rational optimizer, a “ghost” in a bodily machine, began to yield to a notion of a person as an embodied and interactive global workspace (Baars 1997) that is distributed across both interpersonal relationships (attachment theory; Panksepp 1998) and the environment (Clark 1999). Fourth, clinical, cognitive, and transpersonal psychologists (Wilber 1998) began to see the value of studying and using religion in their clinical practices to aid in communication, understanding, and healing.

The net effect of these shifts in perspective on psychological methodology and ontology has been a return to a Jamesian (James 1981) view of human psychology as consisting of a stream of variously conscious and unconscious processes, related to one another in modular ways (Fodor 1983; Weiskrantz 1997), and integrated somewhat haphazardly through the accidents of evolutionary history.

New avenues of exploration for religious psychological states, beliefs, and practices have been opened by these developments in cognitive neuroscience, as well as by new technology. Some of these include:

- (1) Brain scans: studies of the brains of persons engaged in religious activities, through Positron Emission Tomography, Computed Axial Tomography, and Single Photon Emission Computed Tomography (SPECT) scans, and a comparison of the experimental results with base-line brain scans and scans of persons with known pathological conditions such as brain lesions, schizophrenia, and epilepsy.
- (2) First-person methods: Without behaviorist pre-suppositions, methods for systematic and controlled introspection can be studied in a critical but open-minded way.
- (3) Health and integration studies: Studies of the interpersonal and integrative effects of religious experiences, beliefs, or practices are being done in clinical settings.

While it is still possible that the pathologies attributed to religious experience, beliefs, and practices by eliminativists, Freudians, Marxists, and Durkheimians might be corroborated by the emerging twenty-first-century evidence, religious psychology is now at least open to the vindication of religion from charges of pathology. In what follows, samples of each of the previous lines of inquiry into the psychology of religion in cognitive science are cited.

BRAIN SCAN STUDIES

Brain scans of advanced-level meditators, persons suffering from hallucinations, and persons engaged in prayer or other religious ceremonies are being produced by researchers at a variety of universities and institutes. Michael A. Persinger (1993) induced hallucinations in laboratory subjects through stimulation of temporal lobes of the brain. Based on this evidence and reports of religious experience by schizophrenic and epileptic patients, he argues that religious experiences, as hallucina-

tions, are a result of kindling, erratic neuronal stimulation that spreads through sections of the brain. He also reports that enhanced geomagnetic activity and limbic seizures produce religious senses of a “felt presence” and that meditation contributes to intrusive experiences.

In contrast, Eugene G. d’Aquili and Andrew B. Newberg (1999) offer SPECT scans of advanced-level meditators that show changes in regional cerebral blood flow as evidence that alternate circuits of brain activity are developed during meditation. D’Aquili and Newberg discovered that during meditation there is increased activity in the frontal lobes of the brain correlated with decreased activity in the posterior parietal lobes of the brain. They claim that the result is deafferentation of the outward orientation and association areas of the prefrontal cortex, resulting in senses of spacelessness, timelessness, and selflessness typically associated with religious experiences that they characterize as Absolute Unitary Being experiences.

FIRST-PERSON AND INTROSPECTIVE STUDIES

Neurophenomenologists are examining systematic approaches to introspection as a tool of study, using both Husserlian phenomenological techniques and meditative techniques developed in Asian religious traditions, to gain insight into the psychology of religious states of consciousness. The Mind and Life Institute, working at the Keck Laboratory at the University of Wisconsin, Madison, and at the University of Paris, engages in collaborative research between Buddhist meditators and Western neuroscientists, aimed at correlating the Buddhist first-person trained experience of focused attention, open attention, visualization, and compassion, with states of neural phase-symmetry detected on high-density electroencephalography, magnetoencephalography, and functional magnetic resonance imaging. The researchers hope to show that stabilized, trained, first-person experiences of focused attention, compassion, and so on can be systematically correlated to states of neural phase-synchrony that represent states of large-scale integration within the brain.

HEALTH-INTEGRATION STUDIES

Psychologists, such as Mihaly Csikszentmihaly (1997), are studying the relationship between happiness and peak experiences of the type outlined by Abraham Maslow, and are discovering that highly engaged attitudes and relationships, of the type long encouraged by religions, are productive of happiness, or Aristotelian eudaimonia.

In this research self-sacrificing and loving relationships to work and significant others are turning out to produce both happiness and physical and mental health, despite predictions to the contrary made by psychological survivalist and egocentrist theories.

Research groups such as the John Templeton Foundation, the Metanexus Institute, and Stephen G. Post's Institute for Research on Unlimited Love are using methodologies that could be characterized as heterophenomenological to explore the health and social effects of compassionate behavior on human thriving. Also, Division 36 of the American Psychological Association has been sponsoring conferences, several journals (i.e., *International Journal for the Psychology of Religion*, *Journal for the Scientific Study of Religion*, and *Review of Religious Research*), and a newsletter cataloging its members' study of a wide variety of issues related to the clinical and psychological roles of religion in the family, in coping with illness and death, in youth violence, in gender studies, in psychotherapy, in shaping values, and in sociological group formation, among many other topics.

Laura E. Weed (2005)

RELIGION AND MORALITY

Morality is closely associated with religion in the minds of many people. When religious leaders speak out on moral topics, their opinions are often treated with special

deference. They are regarded as moral experts. This raises the question of whether morality depends in some way on religion. Many philosophers have held that it does. John Locke, for example, argued that atheists could not be trusted to be moral because they would not consider themselves obliged even by solemn oaths, much less by ordinary promises. The answer to this question may be of considerable practical importance. If morality does depend on religion, the process of secularization, in the course of which religious belief and practice wither away, seems to pose a serious threat to morality. At one time many social theorists were confident that secularization was inevitable in modern and postmodern societies. Experience has undermined this confidence. Secularization no longer appears to be an inevitable consequence of modernization. Moreover, the process seems to occur at different rates in different modern societies. Thus secularization is more advanced in some Western European societies than it is in the United States. Nevertheless, it seems reasonable to be concerned about whether morality will decline to the extent that modern societies become more secular if it is the case that morality depends on religion.

This entry discusses several ways in which morality may depend on religion. It considers causal, conceptual, epistemological, and metaphysical dependency relations. It also explores the possibility that morality and religion may come into conflict. But a fruitful discussion of how two things are related must rely on some understanding of what those two things are. Hence the entry begins with characterizations of domains of morality and religion.

MORALITY AND RELIGION CIRCUMSCRIBED

Understood in broad terms, morality consists of answers to the general normative question of how one should live one's life. It covers a wide range of topics related to the conduct of human life. Morality concerns actions that should and should not be performed and rules of conduct that should and should not be followed. It also comprehends motives for actions that people should and should not have and character traits or habits that people should and should not try to develop. Another subject of moral concern is ideals of saintliness or heroism to which some people may properly aspire, even though not everyone is called upon to live up to these ideals. Yet another subject is social and political arrangements that people should and should not strive to create or to sustain. Thus understood, morality consists of a diverse array beliefs and practices, and it is probably not possible to give an

illuminating definition of its scope. Philosophers often say that the realm of morality in this broad sense coincides with the realm of the ethical.

When philosophers reflect on the contents of the ethical, they find it useful to distinguish within it two domains, each characterized by a distinctive family of fundamental concepts. One is the axiological domain. Its basic concepts are goodness, badness, and indifference. The other is the deontological domain. Its basic concepts are requirement (obligation), permission (rightness), and prohibition (wrongness). Duty is the chief subject matter of the deontological domain. Some philosophers—Bernard Williams, for example—have proposed that morality be conceived narrowly as restricted to the deontological domain. On this conception, the domain of morality is a proper subdomain of the realm of the ethical.

Discussions of whether morality depends on religion frequently focus exclusively on the deontological domain. It is not hard to see why this occurs. Deontology consists of a system of requirements, permissions, and prohibitions. It is structurally similar to systems of law. Hence it is natural to think of deontology as the domain of moral law. Once this way of thinking has been adopted, the question arises as to whether moral law's binding force depends on the authority of a divine lawgiver. Most of the discussion in this entry will address the issue of whether moral requirements (obligations) and prohibitions (wrongness) depend on a deity of the sort to which the major monotheisms of Judaism, Christianity, and Islam are committed. However, some consideration will also be given to the topic of whether axiological goodness depends on such a deity. For this reason, the narrow conception of morality—which restricts it to the deontological domain—will not be adopted in this entry.

Religion, too, consists of beliefs and practices that exhibit great diversity. Most scholars who study it doubt that the concept of religion can be defined or analyzed in terms of necessary and sufficient conditions for being a religion. Some philosophers—for instance, John Hick—take the concept of religion to be a family-resemblance concept. On this view, religions resemble one another as members of a family resemble one another. For example, the ancient cults of Moloch, Christianity, and Theravada Buddhism may be classified as religions because they resemble one another in various respects, without supposing that all three of them satisfy a single set of necessary and sufficient conditions for being a religion. A more refined version of this view is provided by accounts developed in cognitive psychology of concepts organized

around examples that serve as prototypes or paradigms. As a result of complex patterns of similarity to—and difference from—the prototypes, other cases lie at various distances from the prototypes in a similar space. Cases near the prototypes fall under the concept; cases far enough away from the prototypes do not fall under the concept. In between there may be a gray area in which can be found borderline cases.

In attempting to define the concept of religion in terms of necessary and sufficient conditions, there is often disagreement about whether commitment—in theory or in practice—to superhuman beings is a necessary condition for being a religion. A celebrated debate in anthropology nicely illustrates such disagreement. Melford Spiro made the following proposal: “I shall define ‘religion’ as ‘an institution consisting of culturally patterned interaction with culturally postulated superhuman beings’” (Spiro 1966, p. 96). However, there is an obvious objection to Spiro’s proposal. In its purest form, Theravada Buddhism does not postulate superhuman beings. Yet most scholars think that pure Theravada Buddhism counts as a religion. So Spiro’s proposal fails to provide an adequate necessary condition for being a religion. It is too narrow.

Clifford Geertz (1966) offered a more complex definitional proposal. According to Geertz, “a *religion* is: (1) a system of symbols which acts to (2) establish powerful, pervasive, and long-lasting moods and motivations in men by (3) formulating conceptions of a general order of existence and (4) clothing these conceptions with such an aura of factuality that (5) the moods and motivations seem uniquely realistic” (Geertz 1966, p. 4). Theravada Buddhism will count as a religion by this definition. But so too will the system of symbols characteristic of Nazism, although most scholars wish to classify Nazism as a secular political ideology rather than as a religion—or at least to insist that it is religious only in some extended or analogical sense. Thus Geertz’s proposal fails to provide an adequate sufficient condition for being a religion. It is too broad. Disagreements of this kind fuel skepticism about whether it is possible to frame an illuminating definition of the concept of religion in terms of necessary and sufficient conditions.

For historical reasons, the monotheistic religions of Judaism, Christianity, and Islam are the prototypes of religion for people brought up within European and North American cultures. Discussion in this entry will focus almost entirely on the theism that is common to these paradigmatic religions.

CAUSAL DEPENDENCE

Morality would depend historically on religion if moral beliefs and practices were derived by causal processes from prior religious beliefs and practices. It is often imagined that early human societies had worldviews in which no distinctions were drawn between moral and religious beliefs and practices. All norms of human conduct were then religious in character; their authority was taken to rest on superhuman sources such as the prescriptions of gods. Independent moral beliefs and practices emerged from such religious worldviews in the course of cultural evolution as a result natural processes of functional differentiation. Rules governing the performance of religious rituals, for example, were distinguished from norms of ordinary human social interaction. The idea that all early human societies had tightly integrated worldviews dominated by religious concerns is, of course, highly speculative. There is little direct evidence that supports it. Perhaps studies of tribal societies by anthropologists during the nineteenth and twentieth centuries lend this idea some indirect evidential support. But the inference from structural features of the worldviews of those tribal societies to structural features of the worldviews of early human societies is problematic. After all, when anthropologists encountered them, the tribal societies they studied had themselves been evolving for a long time.
